Methods. By using a combination of evidence- and consensus-based methodologies, guidelines were developed by an expert steering committee in 5 phases, as informed by (1) current scientific evidence (published and unpublished), (2) a series of focus groups, (3) a formal survey, (4) an expert consensus workshop, and (5) draft revision and iteration among members of the steering committee.

Results. Guidelines were developed for youth aged 10 to 21 years and correspond to initial phases of adolescent depression management in primary care, including identification of at-risk youth, assessment and diagnosis, and initial management. The strength of each recommendation and its evidence base are summarized. The identification, assessment, and initial management section of the guidelines includes recommendations for (1) identification of depression in youth at high risk, (2) systematic assessment procedures using reliable depression scales, patient and caregiver interviews, and Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition criteria, (3) patient and family psychoeducation, (4) establishing relevant links in the community, and (5) the establishment of a safety plan.

Conclusions. This part of the guidelines is intended to assist primary care clinicians in the identification and initial management of depressed adolescents in an era of great clinical need and a shortage of mental health specialists but cannot replace clinical judgment; these guidelines are not meant to be the sole source of guidance for adolescent depression management. Additional research that addresses the identification and initial management of depressed youth in primary care is needed, including empirical testing of these guidelines. (11/07)

Guidelines for Adolescent Depression in Primary Care (GLAD-PC): II. Treatment and Ongoing Management

Amy H. Cheung, MD; Rachel A. Zuckerbrot, MD; Peter S. Jensen, MD; Kareem Ghalib, MD; Danielle Laraque, MD; Ruth E. K. Stein, MD; and GLAD-PC Steering Group

ABSTRACT. Objectives. To develop clinical practice guidelines to assist primary care clinicians in the management of adolescent depression. This second part of the guidelines addresses treatment and ongoing management of adolescent depression in the primary care setting.

Methods. Using a combination of evidence- and consensus-based methodologies, guidelines were developed in 5 phases as informed by (1) current scientific evidence (published and unpublished), (2) a series of focus groups,

(3) a formal survey, (4) an expert consensus workshop, and (5) revision and iteration among members of the steering committee.

Results. These guidelines are targeted for youth aged 10 to 21 years and offer recommendations for the management of adolescent depression in primary care, including (1) active monitoring of mildly depressed youth, (2) details for the specific application of evidence-based medication and psychotherapeutic approaches in cases of moderate-to-severe depression, (3) careful monitoring of adverse effects, (4) consultation and coordination of care with mental health specialists, (5) ongoing tracking of outcomes, and (6) specific steps to be taken in instances of partial or no improvement after an initial treatment has begun. The strength of each recommendation and its evidence base are summarized.

Conclusions. These guidelines cannot replace clinical judgment, and they should not be the sole source of guidance for adolescent depression management. Nonetheless, the guidelines may assist primary care clinicians in the management of depressed adolescents in an era of great clinical need and a shortage of mental health specialists. Additional research concerning the management of youth with depression in primary care is needed, including the usability, feasibility, and sustainability of guidelines and determination of the extent to which the guidelines actually improve outcomes of youth with depression. ENDOCARDITIS

Prevention of Infective Endocarditis: Guidelines From the American Heart Association

Walter Wilson, MD, Chair; Kathryn A. Taubert, PhD, FAHA; Michael Gewitz, MD, FAHA; Peter B. Lockhart, DDS; Larry M. Baddour, MD; Matthew Levison, MD; Ann Bolger, MD, FAHA; Christopher H. Cabell, MD, MHS; Masato Takahashi, MD, FAHA; Robert S. Baltimore, MD; Jane W. Newburger, MD, MPH, FAHA; Brian L. Strom, MD; Lloyd Y. Tani, MD; Michael Gerber, MD; Robert O. Bonow, MD, FAHA; Thomas Pallasch, DDS, MS; Stanford T. Shulman, MD, FAHA; Anne H. Rowley, MD; Jane C. Burns, MD; Patricia Ferrieri, MD; Timothy Gardner, MD, FAHA; David Goff, MD, PhD, FAHA; David T. Durack, MD, PhD

ABSTRACT. Background. The purpose of this statement is to update the recommendations by the American Heart Association (AHA) for the prevention of infective endocarditis that were last published in 1997.

Methods and Results. A writing group was appointed by the AHA for their expertise in prevention and treatment of infective endocarditis, with liaison members representing the American Dental Association, the Infectious Diseases Society of America, and the American Academy of Pediatrics. The writing group reviewed input from national and international experts on infective endocarditis. The recommendations in this document reflect analyses of relevant literature regarding procedure-related

bacteremia and infective endocarditis, in vitro susceptibility data of the most common microorganisms that cause infective endocarditis, results of prophylactic studies in animal models of experimental endocarditis, and retrospective and prospective studies of prevention of infective endocarditis. MEDLINE database searches from 1950 to 2006 were done for English-language papers using the following search terms: endocarditis, infective endocarditis, prophylaxis, prevention, antibiotic, antimicrobial, pathogens, organisms, dental, gastrointestinal, genitourinary, streptococcus, enterococcus, staphylococcus, respiratory, dental surgery, pathogenesis, vaccine, immunization, and bacteremia. The reference lists of the identified papers were also searched. We also searched the AHA online library. The American College of Cardiology/AHA classification of recommendations and levels of evidence for practice guidelines were used. The paper was subsequently reviewed by outside experts not affiliated with the writing group and by the AHA Science Advisory and Coordinating Committee.

Conclusions. The major changes in the updated recommendations include the following: (1) The Committee concluded that only an extremely small number of cases of infective endocarditis might be prevented by antibiotic prophylaxis for dental procedures even if such prophylactic therapy were 100% effective. (2) Infective endocarditis prophylaxis for dental procedures should be recommended only for patients with underlying cardiac conditions associated with the highest risk of adverse outcome from infective endocarditis. (3) For patients with these underlying cardiac conditions, prophylaxis is recommended for all dental procedures that involve manipulation of gingival tissue or the periapical region of teeth or perforation of the oral mucosa. (4) Prophylaxis is not recommended based solely on an increased lifetime risk of acquisition of infective endocarditis. (5) Administration of antibiotics solely to prevent endocarditis is not recommended for patients who undergo a genitourinary or gastrointestinal tract procedure. These changes are intended to define more clearly when infective endocarditis prophylaxis is or is not recommended and to provide more uniform and consistent global recommendations. FOOD ALLERGY

Guidelines for the Diagnosis and Management of Food Allergy in the United States: Report of the NIAID-Sponsored Expert Panel
National Institute of Allergy and Infectious Diseases

ABSTRACT. Food allergy is an important public health problem that affects children and adults and may be increasing in prevalence. Despite the risk of severe allergic reactions and even death, there is no current treatment for food allergy: the disease can only be managed by allergen avoidance or treatment of symptoms. The diagnosis and management of food allergy also may vary from one clinical

practice setting to another. Finally, because patients frequently confuse nonallergic food reactions, such as food intolerance, with food allergies, there is an unfounded belief among the public that food allergy prevalence is higher than it truly is. In response to these concerns, the National Institute of Allergy and Infectious Diseases, working with 34 professional organizations, federal agencies, and patient advocacy groups, led the development of clinical guidelines for the diagnosis and management of food allergy. These Guidelines are intended for use by a wide variety of health care professionals, including family practice physicians, clinical specialists, and nurse practitioners. The Guidelines include a consensus definition for food allergy, discuss comorbid conditions often associated with food allergy, and focus on both IgE-mediated and non-IgE-mediated reactions to food. Topics addressed include the epidemiology, natural history, diagnosis, and management of food allergy, as well as the management of severe symptoms and anaphylaxis. These Guidelines provide 43 concise clinical recommendations and additional guidance on points of current controversy in patient management. They also identify gaps in the current scientific knowledge to be addressed through future research. (12/10)

GASTROENTERITIS

Managing Acute Gastroenteritis Among Children: Oral Rehydration, Maintenance, and Nutritional Therapy
Centers for Disease Control and Prevention (11/03)

GASTROESOPHAGEAL REFLUX

Guidelines for Evaluation and Treatment of Gastroesophageal Reflux in Infants and Children
North American Society for Pediatric Gastroenterology, Hepatology, and Nutrition

ABSTRACT. Gastroesophageal reflux (GER), defined as passage of gastric contents into the esophagus, and GER disease (GERD), defined as symptoms or complications of GER, are common pediatric problems encountered by both primary and specialty medical providers. Clinical manifestations of GERD in children include vomiting, poor weight gain, dysphagia, abdominal or substernal pain, esophagitis and respiratory disorders. The GER Guideline Committee of the North American Society for Pediatric Gastroenterology and Nutrition has formulated a clinical practice guideline for the management of pediatric GER. The GER Guideline Committee, consisting of a primary care pediatrician, two clinical epidemiologists (who also practice primary care pediatrics) and five pediatric gastroenterologists, based its recommendations on an integration of a comprehensive and systematic review of the medical literature combined with expert opinion. Consensus was achieved through Nominal Group Technique, a structured quantitative method.

The Committee examined the value of diagnostic tests and treatment modalities commonly used for the management of GERD, and how those interventions can be applied to clinical situations in the infant and older child. The guideline provides recommendations for management by the primary care provider, including evaluation, initial treatment, follow-up management and indications for

consultation by a specialist. The guideline also provides recommendations for management by the pediatric gastroenterologist.

This document represents the official recommendations of the North American Society for Pediatric Gastroenterology and Nutrition on the evaluation and treatment of gastroesophageal reflux in infants and children. The American Academy of Pediatrics has also endorsed these recommendations. The recommendations are summarized in a synopsis within the article. This review and recommendations are a general guideline and are not intended as a substitute for clinical judgment or as a protocol for the management of all patients with this problem. (2001)

GROUP B STREPTOCOCCAL DISEASE

Prevention of Perinatal Group B Streptococcal Disease: Revised Guidelines from CDC, 2010

Centers for Disease Control and Prevention

SUMMARY. Despite substantial progress in prevention of perinatal group B streptococcal (GBS) disease since the 1990s, GBS remains the leading cause of early-onset neonatal sepsis in the United States. In 1996, CDC, in collaboration with relevant professional societies, published guidelines for the prevention of perinatal group B streptococcal disease (CDC. Prevention of perinatal group B streptococcal disease: a public health perspective. *MMWR* 1996;45[No. RR-7]); those guidelines were updated and republished in 2002 (CDC. Prevention of perinatal group B streptococcal disease: revised guidelines from CDC. *MMWR* 2002;51[No. RR-11]). In June 2009, a meeting of clinical and public health representatives was held to reevaluate prevention strategies on the basis of data collected after the issuance of the 2002 guidelines. This report presents CDC's updated guidelines, which have been endorsed by the American College of Obstetricians and Gynecologists, the American Academy of Pediatrics, the American College of Nurse-Midwives, the American Academy of Family Physicians, and the American Society for Microbiology. The recommendations were made on the basis of available evidence when such evidence was sufficient and on expert opinion when available evidence was insufficient. The key changes in the 2010 guidelines include the following:

- expanded recommendations on laboratory methods for the identification of GBS,
- clarification of the colony-count threshold required for reporting GBS detected in the urine of pregnant women,
- updated algorithms for GBS screening and intrapartum chemoprophylaxis for women with preterm labor or preterm premature rupture of membranes,
- a change in the recommended dose of penicillin-G for chemoprophylaxis,
- updated prophylaxis regimens for women with penicillin allergy, and
- a revised algorithm for management of newborns with respect to risk for early-onset GBS disease.

Universal screening at 35–37 weeks' gestation for maternal GBS colonization and use of intrapartum antibiotic

prophylaxis has resulted in substantial reductions in the burden of early-onset GBS disease among newborns. Although early-onset GBS disease has become relatively uncommon in recent years, the rates of maternal GBS colonization (and therefore the risk for early-onset GBS disease in the absence of intrapartum antibiotic prophylaxis) remain unchanged since the 1970s. Continued efforts are needed to sustain and improve on the progress achieved in the prevention of GBS disease. There also is a need to monitor for potential adverse consequences of intrapartum antibiotic prophylaxis (e.g., emergence of bacterial antimicrobial resistance or increased incidence or severity of non-GBS neonatal pathogens). In the absence of a licensed GBS vaccine, universal screening and intrapartum antibiotic prophylaxis continue to be the cornerstones of early-onset GBS disease prevention. (11/10)

HUMAN IMMUNODEFICIENCY VIRUS

Guidelines for the Prevention and Treatment of Opportunistic Infections in HIV-Exposed and HIV-Infected Children

US Department of Health and Human Services

SUMMARY. This report updates the last version of the Guidelines for the Prevention and Treatment of Opportunistic Infections (OIs) in HIV-Exposed and HIV-Infected Children, published in 2009. These guidelines are intended for use by clinicians and other health-care workers providing medical care for HIV-exposed and HIV-infected children in the United States. The guidelines discuss opportunistic pathogens that occur in the United States and ones that might be acquired during international travel, such as malaria. Topic areas covered for each OI include a brief description of the epidemiology, clinical presentation, and diagnosis of the OI in children; prevention of exposure; prevention of first episode of disease; discontinuation of primary prophylaxis after immune reconstitution; treatment of disease; monitoring for adverse effects during treatment, including immune reconstitution inflammatory syndrome (IRIS); management of treatment failure; prevention of disease recurrence; and discontinuation of secondary prophylaxis after immune reconstitution. A separate document providing recommendations for prevention and treatment of OIs among HIV-infected adults and post-pubertal adolescents (*Guidelines for the Prevention and Treatment of Opportunistic Infections in HIV-Infected Adults and Adolescents*) was prepared by a panel of adult HIV and infectious disease specialists (see <http://aidsinfo.nih.gov/guidelines>).

These guidelines were developed by a panel of specialists in pediatric HIV infection and infectious diseases (the Panel on Opportunistic Infections in HIV-Exposed and HIV-Infected Children) from the U.S. government and academic institutions. For each OI, one or more pediatric specialists with subject-matter expertise reviewed the literature for new information since the last guidelines were published and then proposed revised recommendations for review by the full Panel. After these reviews and discussions, the guidelines underwent further revision, with review and approval by the Panel, and final endorsement by the National Institutes of Health (NIH), Centers for Disease Control and Prevention (CDC), the HIV Medicine Association (HIVMA) of the Infectious Diseases Society of America (IDSA), the Pediatric Infectious Disease Society (PIDS), and the American Academy of Pediatrics (AAP). So that readers can ascertain how best to apply the recommendations in their practice environments, the recommendations are rated by a letter that indicates the strength of the recommendation, a Roman numeral that indicates the quality of the evidence supporting the recommendation, and where applicable, a * notation that signifies a hybrid of higher-quality adult study evidence and consistent but lower-quality pediatric study evidence.

More detailed methodologic considerations are listed in Appendix 1 (Important Guidelines Considerations), including a description of the make-up and organizational structure of the Panel, definition of financial disclosure and management of conflict of interest, funding sources for the guidelines, methods of collecting and synthesizing evidence and formulating recommendations, public commentary, and plans for updating the guidelines. The names and financial disclosures for each of the Panel members are listed in Appendices 2 and 3, respectively.

An important mode of childhood acquisition of OIs and HIV infection is from infected mothers. HIV-infected women may be more likely to have coinfections with opportunistic pathogens (e.g., hepatitis C) and more likely than women who are not HIV-infected to transmit these infections to their infants. In addition, HIV-infected women or HIV-infected family members coinfecting with certain opportunistic pathogens may be more likely to transmit these infections horizontally to their children, resulting in increased likelihood of primary acquisition of such infections in young children. Furthermore, transplacental transfer of antibodies that protect infants against serious infections may be lower in HIV-infected women than in women who are HIV-uninfected. Therefore, infections with opportunistic pathogens may affect not just HIV-infected infants but also HIV-exposed, uninfected infants. These guidelines for treating OIs in children, therefore, consider treatment of infections in all children—HIV-infected and HIV-uninfected—born to HIV-infected women.

In addition, HIV infection increasingly is seen in adolescents with perinatal infection who are now surviving into their teens and in youth with behaviorally acquired HIV infection. Guidelines for postpubertal adolescents can be found in the adult OI guidelines, but drug pharmacokinetics (PK) and response to treatment may differ in younger prepubertal or pubertal adolescents. Therefore, these

guidelines also apply to treatment of HIV-infected youth who have not yet completed pubertal development.

Major changes in the guidelines from the previous version in 2009 include:

- Greater emphasis on the importance of antiretroviral therapy (ART) for prevention and treatment of OIs, especially those OIs for which no specific therapy exists;
- Increased information about diagnosis and management of IRIS;
- Information about managing ART in children with OIs, including potential drug-drug interactions;
- Updated immunization recommendations for HIV-exposed and HIV-infected children, including pneumococcal, human papillomavirus, meningococcal, and rotavirus vaccines;
- Addition of sections on influenza, giardiasis, and isosporiasis;
- Elimination of sections on aspergillosis, bartonellosis, and HHV-6 and HHV-7 infections; and
- Updated recommendations on discontinuation of OI prophylaxis after immune reconstitution in children.

The most important recommendations are highlighted in boxed major recommendations preceding each section, and a table of dosing recommendations appears at the end of each section. The guidelines conclude with summary tables that display dosing recommendations for all of the conditions, drug toxicities and drug interactions, and 2 figures describing immunization recommendations for children aged 0 to 6 years and 7 to 18 years.

The terminology for describing use of antiretroviral (ARV) drugs for treatment of HIV infection has been standardized to ensure consistency within the sections of these guidelines and with the *Guidelines for the Use of Antiretroviral Agents in Pediatric HIV Infection*. Combination antiretroviral therapy (cART) indicates use of multiple (generally 3 or more) ARV drugs as part of an HIV treatment regimen that is designed to achieve virologic suppression; highly active antiretroviral therapy (HAART), synonymous with cART, is no longer used and has been replaced by cART; the term ART has been used when referring to use of ARV drugs for HIV treatment more generally, including (mostly historical) use of one- or two-agent ARV regimens that do not meet criteria for cART.

Because treatment of OIs is an evolving science, and availability of new agents or clinical data on existing agents may change therapeutic options and preferences, these recommendations will be periodically updated and will be available at <http://AIDSinfo.nih.gov>. (11/13)

IMMUNOCOMPROMISED HOST

2013 Infectious Diseases Society of America Clinical Practice Guidelines for the Immunization of the Immunocompromised Host

Infectious Diseases Society of America

EXECUTIVE SUMMARY. These guidelines were created to provide primary care and specialty clinicians with evidence-based guidelines for active immunization of patients with altered immunocompetence and their

household contacts in order to safely prevent vaccine-preventable infections. They do not represent the only approach to vaccination. Recommended immunization schedules for normal adults and children as well as certain adults and children at high risk for vaccine-preventable infections are updated and published annually by the Centers for Disease Control and Prevention (CDC) and partner organizations. Some recommendations have not been addressed by the Advisory Committee on Immunization Practices (ACIP) to the CDC or they deviate from recommendations. The goal of presenting these guidelines is to decrease morbidity and mortality from vaccine-preventable infections in immunocompromised patients. Summarized below are the recommendations made by the panel. Supporting tables that provide additional information are available in the electronic version. The panel followed a process used in the development of other Infectious Diseases Society of America guidelines, which included a systematic weighting of the quality of the evidence and the grade of the recommendation (Table 1). The key clinical questions and recommendations are summarized in this executive summary. A detailed description of the methods, background, and evidence summaries that support each recommendation can be found in the full text of the guidelines. (1/14)

INFLUENZA

Seasonal Influenza in Adults and Children—Diagnosis, Treatment, Chemoprophylaxis, and Institutional Outbreak Management: Clinical Practice Guidelines of the Infectious Diseases Society of America

Infectious Diseases Society of America

EXECUTIVE SUMMARY. Background. Influenza virus infection causes significant morbidity and mortality in the United States each year. The majority of persons infected with influenza virus exhibit self-limited, uncomplicated, acute febrile respiratory symptoms or are asymptomatic. However, severe disease and complications due to infection, including hospitalization and death, may occur in elderly persons, in very young persons, in persons with underlying medical conditions (including pulmonary and cardiac disease, diabetes, and immunosuppression), and in previously healthy persons. Early treatment with antiviral medications may reduce the severity and duration of symptoms, hospitalizations, and complications (otitis media, bronchitis, pneumonia), and may reduce the use of outpatient services and antibiotics, extent and quantity of viral shedding, and possibly mortality in certain populations. Vaccination is the best method for preventing influenza, but antivirals may also be used as primary or secondary means of preventing influenza transmission in certain settings.

The Centers for Disease Control and Prevention's (CDC's) Advisory Committee on Immunization Practices and the American Academy of Pediatrics provide recommendations on the appropriate use of trivalent inactivated and live, attenuated influenza vaccines, as well as information on diagnostics and antiviral use for treatment and chemoprophylaxis. The CDC's influenza Web site (<http://www.cdc.gov/flu>) also summarizes up-to-date information on current recommendations for influenza diag-

nostic testing and antiviral use. The Infectious Diseases Society of America's (IDSA's) influenza guideline provides an evidence-based set of recommendations and background on influenza with contributions from many sources, including the CDC, the American Academy of Pediatrics, the American College of Physicians, the American Academy of Family Physicians, the Pediatric Infectious Diseases Society, the Society for Healthcare Epidemiology of America, practicing clinicians, and the IDSA, to guide decision-making on these issues. The current guideline development process included a systematic weighting of the quality of the evidence and the grade of recommendation (table 1). These guidelines apply to seasonal (interpandemic) influenza and not to avian or pandemic disease. Clinical management guidelines for sporadic human infections due to avian A (H5N1) viruses have been published by the World Health Organization. (4/09)

INTRAVASCULAR CATHETER-RELATED INFECTIONS

Guidelines for the Prevention of Intravascular Catheter-Related Infections

Society of Critical Care Medicine, Infectious Diseases Society of America, Society for Healthcare Epidemiology of America, Surgical Infection Society, American College of Chest Physicians, American Thoracic Society, American Society of Critical Care Anesthesiologists, Association for Professionals in Infection Control and Epidemiology, Infusion Nurses Society, Oncology Nursing Society, Society of Cardiovascular and Interventional Radiology, American Academy of Pediatrics, and the Healthcare Infection Control Practices Advisory Committee of the Centers for Disease Control and Prevention

ABSTRACT. These guidelines have been developed for practitioners who insert catheters and for persons responsible for surveillance and control of infections in hospital, outpatient, and home health-care settings. This report was prepared by a working group comprising members from professional organizations representing the disciplines of critical care medicine, infectious diseases, health-care infection control, surgery, anesthesiology, interventional radiology, pulmonary medicine, pediatric medicine, and nursing. The working group was led by the Society of Critical Care Medicine (SCCM), in collaboration with the Infectious Disease Society of America (IDSA), Society for Healthcare Epidemiology of America (SHEA), Surgical Infection Society (SIS), American College of Chest Physicians (ACCP), American Thoracic Society (ATS), American Society of Critical Care Anesthesiologists (ASCCA), Association for Professionals in Infection Control and Epidemiology (APIC), Infusion Nurses Society (INS), Oncology Nursing Society (ONS), Society of Cardiovascular and Interventional Radiology (SCVIR), American Academy of Pediatrics (AAP), and the Healthcare Infection Control Practices Advisory Committee (HICPAC) of the Centers for Disease Control and Prevention (CDC) and is intended to replace the *Guideline for Prevention of Intravascular Device-Related Infections* published in 1996. These guidelines are intended to provide evidence-based recommendations for preventing catheter-related infections. Major areas of emphasis include 1) educating and training health-care providers

who insert and maintain catheters; 2) using maximal sterile barrier precautions during central venous catheter insertion; 3) using a 2% chlorhexidine preparation for skin antisepsis; 4) avoiding routine replacement of central venous catheters as a strategy to prevent infection; and 5) using antiseptic/antibiotic impregnated short-term central venous catheters if the rate of infection is high despite adherence to other strategies (ie, education and training, maximal sterile barrier precautions, and 2% chlorhexidine for skin antisepsis). These guidelines also identify performance indicators that can be used locally by health-care institutions or organizations to monitor their success in implementing these evidence-based recommendations. (11/02)

JAUNDICE

Guideline for the Evaluation of Cholestatic Jaundice in Infants

North American Society for Pediatric Gastroenterology, Hepatology, and Nutrition

ABSTRACT. For the primary care provider, cholestatic jaundice in infancy, defined as jaundice caused by an elevated conjugated bilirubin, is an uncommon but potentially serious problem that indicates hepatobiliary dysfunction. Early detection of cholestatic jaundice by the primary care physician and timely, accurate diagnosis by the pediatric gastroenterologist are important for successful treatment and a favorable prognosis. The Cholestasis Guideline Committee of the North American Society for Pediatric Gastroenterology, Hepatology and Nutrition has formulated a clinical practice guideline for the diagnostic evaluation of cholestatic jaundice in the infant. The Cholestasis Guideline Committee, consisting of a primary care pediatrician, a clinical epidemiologist (who also practices primary care pediatrics), and five pediatric gastroenterologists, based its recommendations on a comprehensive and systematic review of the medical literature integrated with expert opinion. Consensus was achieved through the Nominal Group Technique, a structured quantitative method.

The Committee examined the value of diagnostic tests commonly used for the evaluation of cholestatic jaundice and how those interventions can be applied to clinical situations in the infant. The guideline provides recommendations for management by the primary care provider, indications for consultation by a pediatric gastroenterologist, and recommendations for management by the pediatric gastroenterologist.

The Cholestasis Guideline Committee recommends that any infant noted to be jaundiced at 2 weeks of age be evaluated for cholestasis with measurement of total and direct serum bilirubin. However, breast-fed infants who can be reliably monitored and who have an otherwise normal history (no dark urine or light stools) and physical examination may be asked to return at 3 weeks of age and, if jaundice persists, have measurement of total and direct serum bilirubin at that time.

This document represents the official recommendations of the North American Society for Pediatric Gastroenterology, Hepatology and Nutrition on the evaluation of cholestatic jaundice in infants. The American Academy of Pediatrics

has also endorsed these recommendations. These recommendations are a general guideline and are not intended as a substitute for clinical judgment or as a protocol for the care of all patients with this problem. (8/04)

METHICILLIN-RESISTANT *STAPHYLOCOCCUS AUREUS*

Clinical Practice Guidelines by the Infectious Diseases Society of America for the Treatment of Methicillin-Resistant *Staphylococcus aureus* Infections in Adults and Children

Infectious Diseases Society of America

ABSTRACT. Evidence-based guidelines for the management of patients with methicillin-resistant *Staphylococcus aureus* (MRSA) infections were prepared by an Expert Panel of the Infectious Diseases Society of America (IDSA). The guidelines are intended for use by health care providers who care for adult and pediatric patients with MRSA infections. The guidelines discuss the management of a variety of clinical syndromes associated with MRSA disease, including skin and soft tissue infections (SSTI), bacteremia and endocarditis, pneumonia, bone and joint infections, and central nervous system (CNS) infections. Recommendations are provided regarding vancomycin dosing and monitoring, management of infections due to MRSA strains with reduced susceptibility to vancomycin, and vancomycin treatment failures. MIGRAINE HEADACHE

Pharmacological Treatment of Migraine Headache in Children and Adolescents

Quality Standards Subcommittee of the American Academy of Neurology and the Practice Committee of the Child Neurology Society (12/04)

PALLIATIVE CARE

Clinical Practice Guidelines for Quality Palliative Care, Third Edition

National Consensus Project for Quality Palliative Care (2013)

RADIOLOGY

Neuroimaging of the Neonate

Quality Standards Subcommittee of the American Academy of Neurology and the Practice Committee of the Child Neurology Society

ABSTRACT. Objective. The authors reviewed available evidence on neonatal neuroimaging strategies for evaluating both very low birth weight preterm infants and encephalopathic term neonates.

Imaging for the Preterm Neonate. Routine screening cranial ultrasonography (US) should be performed on all infants of <30 weeks' gestation once between 7 and 14 days of age and should be optimally repeated between 36 and 40 weeks' postmenstrual age. This strategy detects lesions such as intraventricular hemorrhage, which influences clinical care, and those such as periventricular leukomalacia and low-pressure ventriculomegaly, which provide information about long-term neurodevelopmental outcome. There is insufficient evidence for routine MRI of all very low birth weight preterm infants with abnormal results of cranial US.

Imaging for the Term Infant. Noncontrast CT should be performed to detect hemorrhagic lesions in the encephalopathic term infant with a history of birth trauma, low hematocrit, or coagulopathy. If CT findings are inconclusive, MRI should be performed between days 2 and 8 to assess the location and extent of injury. The pattern of injury identified with conventional MRI may provide diagnostic and prognostic information for term infants with evidence of encephalopathy. In particular, basal ganglia and thalamic lesions detected by conventional MRI are associated with poor neurodevelopmental outcome. Diffusion-weighted imaging may allow earlier detection of these cerebral injuries.

Recommendations. US plays an established role in the management of preterm neonates of <30 weeks' gestation. US also provides valuable prognostic information when the infant reaches 40 weeks' postmenstrual age. For encephalopathic term infants, early CT should be used to exclude hemorrhage; MRI should be performed later in the first postnatal week to establish the pattern of injury and predict neurologic outcome. (6/02)

SEDATION AND ANALGESIA

Clinical Policy: Evidence-based Approach to Pharmacologic Agents Used in Pediatric Sedation and Analgesia in the Emergency Department

American College of Emergency Physicians (10/04)

SEIZURE

Evaluating a First Nonfebrile Seizure in Children
Quality Standards Subcommittee of the American Academy of Neurology, the Child Neurology Society, and the American Epilepsy Society

ABSTRACT. Objective. The Quality Standards Subcommittee of the American Academy of Neurology develops practice parameters as strategies for patient management based on analysis of evidence. For this practice parameter, the authors reviewed available evidence on evaluation of the first nonfebrile seizure in children in order to make practice recommendations based on this available evidence. **Methods:** Multiple searches revealed relevant literature and each article was reviewed, abstracted, and classified. Recommendations were based on a three-tiered scheme of classification of the evidence. **Results:** Routine EEG as part of the diagnostic evaluation was recommended; other studies such as laboratory evaluations and neuroimaging studies were recommended as based on specific clinical circumstances. **Conclusions:** Further studies are needed using large, well-characterized samples and standardized data collection instruments. Collection of data regarding appropriate timing of evaluations would be important. (8/00)

Treatment of the Child With a First Unprovoked Seizure
Quality Standards Subcommittee of the American Academy of Neurology and the Practice Committee of the Child Neurology Society

ABSTRACT. The Quality Standards Subcommittee of the American Academy of Neurology and the Practice Committee of the Child Neurology Society develop practice parameters as strategies for patient management

based on analysis of evidence regarding risks and benefits. This parameter reviews published literature relevant to the decision to begin treatment after a child or adolescent experiences a first unprovoked seizure and presents evidence-based practice recommendations. Reasons why treatment may be considered are discussed. Evidence is reviewed concerning risk of recurrence as well as effect of treatment on prevention of recurrence and development of chronic epilepsy. Studies of side effects of anticonvulsants commonly used to treat seizures in children are also reviewed. Relevant articles are classified according to the Quality Standards Subcommittee classification scheme. Treatment after a first unprovoked seizure appears to decrease the risk of a second seizure, but there are few data from studies involving only children. There appears to be no benefit of treatment with regard to the prognosis for long-term seizure remission. Antiepileptic drugs (AED) carry risks of side effects that are particularly important in children. The decision as to whether or not to treat children and adolescents who have experienced a first unprovoked seizure must be based on a risk-benefit assessment that weighs the risk of having another seizure against the risk of chronic AED therapy. The decision should be individualized and take into account both medical issues and patient and family preference. (1/03)

STATUS EPILEPTICUS

Diagnostic Assessment of the Child With Status Epilepticus (An Evidence-based Review)

Quality Standards Subcommittee of the American Academy of Neurology and the Practice Committee of the Child Neurology Society

ABSTRACT. Objective. To review evidence on the assessment of the child with status epilepticus (SE).

Methods. Relevant literature were reviewed, abstracted, and classified. When data were missing, a minimum diagnostic yield was calculated. Recommendations were based on a four-tiered scheme of evidence classification.

Results. Laboratory studies (Na⁺ or other electrolytes, Ca⁺⁺, glucose) were abnormal in approximately 6% and are generally ordered as routine practice. When blood or spinal fluid cultures were done on these children, blood cultures were abnormal in at least 2.5% and a CNS infection was found in at least 12.8%. When antiepileptic drug (AED) levels were ordered in known epileptic children already taking AEDs, the levels were low in 32%. A total of 3.6% of children had evidence of ingestion. When studies for inborn errors of metabolism were done, an abnormality was found in 4.2%. Epileptiform abnormalities occurred in 43% of EEGs of children with SE and helped determine the nature and location of precipitating electroconvulsive events (8% generalized, 16% focal, and 19% both). Abnormalities on neuroimaging studies that may explain the etiology of SE were found in at least 8% of children.

Recommendations. Although common clinical practice is that blood cultures and lumbar puncture are obtained if there is a clinical suspicion of a systemic or CNS infection, there are insufficient data to support or refute recommendations as to whether blood cultures or lumbar

puncture should be done on a routine basis in children in whom there is no clinical suspicion of a systemic or CNS infection (Level U). AED levels should be considered when a child with treated epilepsy develops SE (Level B). Toxicology studies and metabolic studies for inborn errors of metabolism may be considered in children with SE when there are clinical indicators for concern or when the initial evaluation reveals no etiology (Level C). An EEG may be considered in a child with SE as it may be helpful in determining whether there are focal or generalized epileptiform abnormalities that may guide further testing for the etiology of SE, when there is a suspicion of pseudostatus epilepticus (nonepileptic SE), or nonconvulsive SE, and may guide treatment (Level C). Neuroimaging may be considered after the child with SE has been stabilized if there are clinical indications or if the etiology is unknown (Level C). There is insufficient evidence to support or refute routine neuroimaging in a child presenting with SE (Level U). (11/06)

TOBACCO USE

Treating Tobacco Use and Dependence: 2008 Update
US Department of Health and Human Services

ABSTRACT. *Treating Tobacco Use and Dependence: 2008 Update*, a Public Health Service-sponsored Clinical Practice Guideline, is a product of the Tobacco Use and Dependence Guideline Panel ("the Panel"), consortium representatives, consultants, and staff. These 37 individuals were charged with the responsibility of identifying effective, experimentally validated tobacco dependence treatments and practices. The updated Guideline was sponsored by a consortium of eight Federal Government and nonprofit organizations: the Agency for Healthcare Research and Quality (AHRQ); Centers for Disease Control and Prevention (CDC); National Cancer Institute (NCI); National Heart, Lung, and Blood Institute (NHLBI); National Institute on Drug Abuse (NIDA); American Legacy Foundation; Robert Wood Johnson Foundation (RWJF); and University of Wisconsin School of Medicine and Public Health's Center for Tobacco Research and Intervention (UW-CTRI). This Guideline is an updated version of the 2000 *Treating Tobacco Use and Dependence: Clinical Practice Guideline* that was sponsored by the U.S. Public Health Service, U. S. Department of Health and Human Services.

An impetus for this Guideline update was the expanding literature on tobacco dependence and its treatment. The original 1996 Guideline was based on some 3,000 articles on tobacco treatment published between 1975 and 1994. The 2000 Guideline entailed the collection and screening of an additional 3,000 articles published between 1995 and 1999. The 2008 Guideline update screened an additional 2,700 articles; thus, the present Guideline update reflects the distillation of a literature base of more than 8,700 research articles. Of course, this body of research was further reviewed to identify a much smaller group of articles that served as the basis for focused Guideline data analyses and review.

This Guideline contains strategies and recommendations designed to assist clinicians; tobacco dependence treatment specialists; and health care administrators,

insurers, and purchasers in delivering and supporting effective treatments for tobacco use and dependence. The recommendations were made as a result of a systematic review and meta-analysis of 11 specific topics identified by the Panel (proactive quitlines; combining counseling and medication relative to either counseling or medication alone; varenicline; various medication combinations; long-term medications; cessation interventions for individuals with low socioeconomic status/limited formal education; cessation interventions for adolescent smokers; cessation interventions for pregnant smokers; cessation interventions for individuals with psychiatric disorders, including substance use disorders; providing cessation interventions as a health benefit; and systems interventions, including provider training and the combination of training and systems interventions). The strength of evidence that served as the basis for each recommendation is indicated clearly in the Guideline update. A draft of the Guideline update was peer reviewed prior to publication, and the input of 81 external reviewers was considered by the Panel prior to preparing the final document. In addition, the public had an opportunity to comment through a *Federal Register* review process. The key recommendations of the updated Guideline, *Treating Tobacco Use and Dependence: 2008 Update*, based on the literature review and expert Panel opinion, are as follows:

Ten Key Guideline Recommendations

The overarching goal of these recommendations is that clinicians strongly recommend the use of effective tobacco dependence counseling and medication treatments to their patients who use tobacco, and that health systems, insurers, and purchasers assist clinicians in making such effective treatments available.

1. Tobacco dependence is a chronic disease that often requires repeated intervention and multiple attempts to quit. Effective treatments exist, however, that can significantly increase rates of long-term abstinence.
2. It is essential that clinicians and health care delivery systems consistently identify and document tobacco use status and treat every tobacco user seen in a health care setting.
3. Tobacco dependence treatments are effective across a broad range of populations. Clinicians should encourage every patient willing to make a quit attempt to use the counseling treatments and medications recommended in this Guideline.
4. Brief tobacco dependence treatment is effective. Clinicians should offer every patient who uses tobacco at least the brief treatments shown to be effective in this Guideline.
5. Individual, group, and telephone counseling are effective, and their effectiveness increases with treatment intensity. Two components of counseling are especially effective, and clinicians should use these when counseling patients making a quit attempt:
 - Practical counseling (problem solving/skills training)
 - Social support delivered as part of treatment

6. Numerous effective medications are available for tobacco dependence, and clinicians should encourage their use by all patients attempting to quit smoking—except when medically contraindicated or with specific populations for which there is insufficient evidence of effectiveness (i.e., pregnant women, smokeless tobacco users, light smokers, and adolescents).
 - Seven first-line medications (5 nicotine and 2 non-nicotine) reliably increase long-term smoking abstinence rates:
 - Bupropion SR
 - Nicotine gum
 - Nicotine inhaler
 - Nicotine lozenge
 - Nicotine nasal spray
 - Nicotine patch
 - Varenicline
 - Clinicians also should consider the use of certain combinations of medications identified as effective in this Guideline.
7. Counseling and medication are effective when used by themselves for treating tobacco dependence. The combination of counseling and medication, however, is more effective than either alone. Thus, clinicians should encourage all individuals making a quit attempt to use both counseling and medication.
8. Telephone quitline counseling is effective with diverse populations and has broad reach. Therefore, both clinicians and health care delivery systems should ensure patient access to quitlines and promote quitline use.
9. If a tobacco user currently is unwilling to make a quit attempt, clinicians should use the motivational treatments shown in this Guideline to be effective in increasing future quit attempts.
10. Tobacco dependence treatments are both clinically effective and highly cost-effective relative to interventions for other clinical disorders. Providing coverage for these treatments increases quit rates. Insurers and purchasers should ensure that all insurance plans include the counseling and medication identified as effective in this Guideline as covered benefits.

The updated Guideline is divided into seven chapters that provide an overview, including methods (Chapter 1); information on the assessment of tobacco use (Chapter 2); clinical interventions, both for patients willing and unwilling to make a quit attempt at this time (Chapter 3); intensive interventions (Chapter 4); systems interventions for health care administrators, insurers, and purchasers (Chapter 5); the scientific evidence supporting the Guideline recommendations (Chapter 6); and information relevant to specific populations and other topics (Chapter 7).

A comparison of the findings of the updated Guideline with the 2000 Guideline reveals the considerable progress made in tobacco research over the brief period separating these two publications. Tobacco dependence increasingly is recognized as a chronic disease, one that typically requires ongoing assessment and repeated intervention. In addition, the updated Guideline offers the clinician many more effective treatment strategies than were identified in the original Guideline. There now are seven different first-line effective agents in the smoking cessation pharmacopoeia, allowing the clinician and patient many different medication options. In addition, recent evidence provides even stronger support for counseling (both when used alone and with other treatments) as an effective tobacco cessation strategy; counseling adds to the effectiveness of tobacco cessation medications, quitline counseling is an effective intervention with a broad reach, and counseling increases tobacco cessation among adolescent smokers.

Finally, there is increasing evidence that the success of any tobacco dependence treatment strategy cannot be divorced from the health care system in which it is embedded. The updated Guideline contains new evidence that health care policies significantly affect the likelihood that smokers will receive effective tobacco dependence treatment and successfully stop tobacco use. For instance, making tobacco dependence treatment a covered benefit of insurance plans increases the likelihood that a tobacco user will receive treatment and quit successfully. Data strongly indicate that effective tobacco interventions require coordinated interventions. Just as the clinician must intervene with his or her patient, so must the health care administrator, insurer, and purchaser foster and support tobacco intervention as an integral element of health care delivery. Health care administrators and insurers should ensure that clinicians have the training and support to deliver consistent, effective intervention to tobacco users.

One important conclusion of this Guideline update is that the most effective way to move clinicians to intervene is to provide them with information regarding multiple effective treatment options and to ensure that they have ample institutional support to use these options. Joint actions by clinicians, administrators, insurers, and purchasers can encourage a culture of health care in which failure to intervene with a tobacco user is inconsistent with standards of care. SECTION 3

Affirmation of Value Clinical Practice Guidelines

.....

These guidelines are not endorsed as policy of the American Academy of Pediatrics (AAP). Documents that lack a clear description of the process for identifying, assessing, and incorporating research evidence are not eligible for AAP endorsement as practice guidelines. However, such documents may be of educational value to members of the AAP.

ASTHMA

Environmental Management of Pediatric Asthma:
Guidelines for Health Care Providers
National Environmental Education Foundation

INTRODUCTION (EXCERPT). These guidelines are the product of a new Pediatric Asthma Initiative aimed at integrating environmental management of asthma into pediatric health care. This document outlines competencies in environmental health relevant to pediatric asthma that should be mastered by primary health care providers, and outlines the environmental interventions that should be communicated to patients.

These environmental management guidelines were developed for pediatricians, family physicians, internists, pediatric nurse practitioners, pediatric nurses, and physician assistants. In addition, these guidelines should be integrated into respiratory therapists' and licensed case/care (LICSW) management professionals' education and training.

The guidelines contain three components:

- **Competencies:** An outline of the knowledge and skills that health care providers and health professional students should master and demonstrate in order to incorporate management of environmental asthma triggers into pediatric practice.
- **Environmental History Form:** A quick, easy, user-friendly document that can be utilized as an intake tool by the health care provider to help determine pediatric patients' environmental asthma triggers.
- **Environmental Intervention Guidelines:** Follow-up questions and intervention solutions to environmental asthma triggers. (8/05)

TURNER SYNDROME

Care of Girls and Women With Turner Syndrome:
A Guideline of the Turner Syndrome Study Group
Turner Syndrome Consensus Study Group

ABSTRACT. Objectives. The objective of this work is to provide updated guidelines for the evaluation and treatment of girls and women with Turner syndrome (TS).

Participants. The Turner Syndrome Consensus Study Group is a multidisciplinary panel of experts with relevant clinical and research experience with TS that met in Bethesda, Maryland, April 2006. The meeting was supported by the National Institute of Child Health and unrestricted educational grants from pharmaceutical companies.

Evidence. The study group used peer-reviewed published information to form its principal recommendations. Expert opinion was used where good evidence was lacking.

Consensus. The study group met for 3 d to discuss key issues. Breakout groups focused on genetic, cardiological, auxological, psychological, gynecological, and general medical concerns and drafted recommendations for presentation to the whole group. Draft reports were available for additional comment on the meeting web site. Synthesis of the section reports and final revisions were reviewed by e-mail and approved by whole-group consensus.

Conclusions. We suggest that parents receiving a prenatal diagnosis of TS be advised of the broad phenotypic spectrum and the good quality of life observed in TS in recent years. We recommend that magnetic resonance angiography be used in addition to echocardiography to evaluate the cardiovascular system and suggest that patients with defined cardiovascular defects be cautioned in regard to pregnancy and certain types of exercise. We recommend that puberty should not be delayed to promote statural growth. We suggest a comprehensive educational evaluation in early childhood to identify potential attention-deficit or nonverbal learning disorders. We suggest that caregivers address the prospect of premature ovarian failure in an open and sensitive manner and emphasize the critical importance of estrogen treatment for feminization and for bone health during the adult years. All individuals with TS require continued monitoring of hearing and thyroid function throughout the lifespan. We suggest that adults with TS be monitored for aortic enlargement, hypertension, diabetes, and dyslipidemia. (1/07)

BACKGROUND INFORMATION TO SUPPORT AMERICAN ACADEMY OF PEDIATRICS POLICY

*Includes policy statements, clinical reports, and technical reports
published between January 1, 2014, and January 1, 2015.*

INTRODUCTION

This section of *Pediatric Clinical Practice Guidelines & Policies: A Compendium of Evidence-based Research for Pediatric Practice* is composed of policy statements, clinical reports, and technical reports issued by the American Academy of Pediatrics (AAP) and is designed as a quick reference tool for AAP members, AAP staff, and other interested parties. Section 4 includes the full text of all AAP policies published in 2014. Section 5 is a compilation of all active AAP statements (through January 1, 2015) arranged alphabetically, with abstracts where applicable. A committee index (Appendix 1) and subject index are also available. The companion CD-ROM contains the full text of all current policy statements, clinical reports, and technical reports (through January 1, 2015). These materials should help answer questions that arise about the AAP position on child health care issues. **However, remember that AAP policy statements, clinical reports, and technical reports do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.**

Policy statements have been written by AAP committees, councils, task forces, or sections and approved by the AAP Board of Directors. Most of these statements have appeared previously in *Pediatrics*, *AAP News*, or *News & Comments* (the forerunner of *AAP News*).

This section does not contain all AAP policies. It does not include

- Press releases.
- Motions and resolutions that were approved by the Board of Directors. These can be found in the Board of Directors' minutes.
- Policies in manuals, pamphlets, booklets, or other AAP publications. These items can be ordered through the AAP. To order, visit shop.aap.org/books/ or call toll-free 888/227-1770.
- Testimony before Congress or government agencies.

All policy statements, clinical reports, and technical reports from the American Academy of Pediatrics automatically expire 5 years after publication unless reaffirmed, revised, or retired at or before that time. Please check the American Academy of Pediatrics Web site at www.aap.org for up-to-date reaffirmations, revisions, and retirements..

2014 Recommendations for Preventive Pediatric Health Care

Bright Futures/American Academy of Pediatrics

Each child and family is unique; therefore, these Recommendations for Preventive Pediatric Health Care are designed for the care of children who are receiving competent parenting, have no manifestations of any important health problems, and are growing and developing in satisfactory fashion. Additional visits may become necessary if circumstances suggest variations from normal.

Developmental, psychosocial, and chronic disease issues for children and adolescents may require frequent counseling and treatment visits separate from preventive care visits.

These guidelines represent a consensus by the American Academy of Pediatrics (AAP) and Bright Futures. The AAP continues to emphasize the great importance of continuity of care in comprehensive health supervision and the need to avoid fragmentation of care.

Refer to the specific guidance by age as listed in *Bright Futures* guidelines (Hagan JF, Shaw JS, Duncan PM, eds. *Bright Futures Guidelines for Health Supervision of Infants, Children and Adolescents*. 3rd ed. Elk Grove Village, IL: American Academy of Pediatrics; 2008).

The recommendations in this statement do not indicate an exclusive course of treatment or standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

- If a child comes under care for the first time at any point on the schedule, or if any items are not accomplished at the suggested age, the schedule should be brought up to date at the earliest possible time.
- A prenatal visit is recommended for parents who are at high risk, for first-time parents, and for those who request a conference. The prenatal visit should include anticipatory guidance, pertinent medical history, and a discussion of benefits of breastfeeding and planned method of feeding, per the 2009 AAP statement "The Prenatal Visit" (<http://pediatrics.aappublications.org/content/124/4/1227.full>).
- Every infant should have a newborn evaluation after birth, and breastfeeding should be encouraged (instruction and support should be offered).
- Every infant should have an evaluation within 3 to 5 days of birth and within 48 to 72 hours after discharge from the hospital to include evaluation for feeding and jaundice. Breastfeeding infants should receive formal breastfeeding evaluation, and their mothers should receive encouragement and instruction, as recommended in the 2012 AAP statement "Breastfeeding and the Use of Human Milk" (<http://pediatrics.aappublications.org/content/129/3/582.full>). Newborn infants discharged less than 48 hours after delivery must be examined within 48 hours of discharge, per the 2010 AAP statement "Hospital Stay for Healthy Term Newborns" (<http://pediatrics.aappublications.org/content/125/2/405.full>).
- Screen, per the 2007 AAP statement "Expert Committee Recommendations Regarding the Prevention, Assessment, and Treatment of Child and Adolescent Overweight and Obesity: Summary Report" (http://pediatrics.aappublications.org/content/120/Supplement_4/S164.full).
- Blood pressure measurement in infants and children with specific risk conditions should be performed at visits before age 3 years.
- If the patient is uncooperative, rescreen within 6 months, per the 2007 AAP statement "Eye Examination in Infants, Children, and Young Adults by Pediatricians" (<http://pediatrics.aappublications.org/content/111/4/902.abstract>).
- All newborns should be screened, per the AAP statement "New 2007 Position Statement: Principles and Guidelines for Early Hearing Detection and Intervention Programs" (<http://pediatrics.aappublications.org/content/120/4/998.full>).
- See 2006 AAP statement "Identifying Infants and Young Children With Developmental Disorders in the Medical Home: An Algorithm for Developmental Surveillance and Screening" (<http://pediatrics.aappublications.org/content/118/1/405.full>).
- Screening should occur per the 2007 AAP statement "Identification and Evaluation of Children with Autism Spectrum Disorders" (<http://pediatrics.aappublications.org/content/120/5/1183.full>).

- A recommended screening tool is available at <http://www.caesar-boston.org/CRAFFT/index.php>.
- Recommended screening using the Patient Health Questionnaire (PHQ-2) or other tools available in the GLAD-PC toolkit and at http://www.aap.org/en-us/advocacy-and-policy/aap-health-initiatives/Mental-Health/Documents/MH_ScreeningChart.pdf.
- At each visit, age-appropriate physical examination is essential, with infant totally unclothed and older children undressed and suitably draped. See 2011 AAP statement "Use of Chaperones During the Physical Examination of the Pediatric Patient" (<http://pediatrics.aappublications.org/content/127/5/991.full>).
- These may be modified, depending on entry point into schedule and individual need.
- The Recommended Uniform Newborn Screening Panel (<http://www.hhsa.gov/advisory-committees/ncmb/advisory-panel/recommended-panel/uniform-screening-panel.pdf>), as determined by The Secretary's Advisory Committee on Heritable Disorders in Newborns and Children, and state newborn screening laws/regulations (<http://genes-c-usa.hhsa.gov/sites/genes-c-usa/files/ncmborders.pdf>), establish the criteria for and coverage of newborn screening procedures and programs. Follow-up must be provided, as appropriate, by the pediatrician.
- Screening for critical congenital heart disease using pulse oximetry should be performed in newborns, after 24 hours of age, before discharge from the hospital, per the 2011 AAP statement "Endorsement of Health and Human Services Recommendation for Pulse Oximetry Screening for Critical Congenital Heart Disease" (<http://pediatrics.aappublications.org/content/129/1/190.full>).
- Schedules, per the AAP Committee on Infectious Diseases, are available at: <http://aapredbook.aappublications.org/site/resources/zschedules.shtml>. Every visit should be an opportunity to update and complete a child's immunizations.
- See 2010 AAP statement "Diagnosis and Prevention of Iron Deficiency and Iron Deficiency Anemia in Infants and Young Children (0-3 Years of Age)" (<http://pediatrics.aappublications.org/content/126/5/1040.full>).
- For children at risk of lead exposure, see the 2012 CDC Advisory Committee on Childhood Lead Poisoning Prevention statement "Low Level Lead Exposure Harms Children: A Renewed Call for Primary Prevention" (http://www.cdc.gov/nceh/lead/ACCLPP/Final_Document_030712.pdf).

- Perform risk assessments or screenings as appropriate, based on universal screening requirements for patients with Medicaid or in high prevalence areas.
- Tuberculosis testing per recommendations of the Committee on Infectious Diseases, published in the current edition of *Red Book: Report of the Committee on Infectious Diseases*. Testing should be performed on recognition of high-risk factors.
- See AAP-endorsed 2011 guidelines from the National Heart Blood and Lung Institute, "Integrated Guidelines for Cardiovascular Health and Risk Reduction in Children and Adolescents" (http://www.nhlbi.nih.gov/guidelines/cvdr_ped/index.htm).
- Adolescents should be screened for sexually transmitted infections (STIs) per recommendations in the current edition of the *AAP Red Book: Report of the Committee on Infectious Diseases*. Additionally, all adolescents should be screened for HIV according to the AAP statement (<http://pediatrics.aappublications.org/content/128/5/1023.full>) once between the ages of 16 and 18, making every effort to preserve confidentiality of the adolescent. Those at increased risk of HIV infection, including those who are sexually active, participate in injection drug use, or are being tested for other STIs, should be tested for HIV and reassessed annually.
- See USPSTF recommendations (<http://www.uspreventiveservicestaskforce.org/uspstf/uspserv.htm>). Indications for pelvic examinations prior to age 21 are noted in the 2010 AAP statement "Gynecologic Examination for Adolescents in the Pediatric Office Setting" (<http://pediatrics.aappublications.org/content/126/3/580.full>).
- Refer to a dental home, if available. If not available, perform a risk assessment (<http://www2.aap.org/oralhealth/docs/RiskAssessmentTool.pdf>). If primary water source is deficient in fluoride, consider oral fluoride supplementation. For those at high risk, consider application of fluoride varnish for caries prevention. See 2008 AAP statement "Preventive Oral Health Intervention for Pediatricians" (<http://pediatrics.aappublications.org/content/122/6/1387.full>) and 2009 AAP statement "Oral Health Risk Assessment: Timing and Establishment of the Dental Home" (<http://pediatrics.aappublications.org/content/111/5/1113.full>).

Summary of changes made to the 2014 AAP Recommendations for Preventive Pediatric Health Care (Periodicity Schedule)

Changes to Developmental/Behavioral Assessment

- **Alcohol and Drug Use Assessment-** Information regarding a recommended screening tool (CRAFTT) was added.
- **Depression-** Screening for depression at ages 11 through 21 has been added, along with suggested screening tools.

Changes to Procedures

- **Dyslipidemia screening-** An additional screening between 9 and 11 years of age has been added. The reference has been updated to the AAP-endorsed National Heart Blood and Lung Institute policy (http://www.nhlbi.nih.gov/guidelines/cvd_ped/index.htm).
- **Hematocrit or hemoglobin-** A risk assessment has been added at 15 and 30 months. The reference has been updated to the current AAP policy (<http://pediatrics.aappublications.org/content/126/5/1040.full>).
- **STI/HIV screening-** A screen for HIV has been added between 16 and 18 years. Information on screening adolescents for HIV has been added in the footnotes. STI screening now references recommendations made in the AAP Red Book. This category was previously titled "STI Screening."
- **Cervical dysplasia-** Adolescents should no longer be routinely screened for cervical dysplasia until age 21. Indications for pelvic exams prior to age 21 are noted in the 2010 AAP statement "Gynecologic Examination for Adolescents in the Pediatric Office Setting" (<http://pediatrics.aappublications.org/content/126/3/583.full>).
- **Critical Congenital Heart Disease-** Screening for critical congenital heart disease using pulse oximetry should be performed in newborns, after 24 hours of age, before discharge from the hospital, per the 2011 AAP statement, "Endorsement of Health and Human Services Recommendation for Pulse Oximetry Screening for Critical Congenital Heart Disease" (<http://pediatrics.aappublications.org/content/129/1/190.full>).

For several recommendations, the AAP Policy has been updated since 2007 but there have been no changes in the timing of recommendations on the Periodicity Schedule. These include:

- Footnote 2- The Prenatal Visit (2009): <http://pediatrics.aappublications.org/content/124/4/1227.full>
- Footnote 4- Breastfeeding and the Use of Human Milk (2012): <http://pediatrics.aappublications.org/content/129/3/e827.full> and Hospital Stay for Healthy Term Newborns (2010): <http://pediatrics.aappublications.org/content/125/2/405.full>
- Footnote 8- Year 2007 Position Statement: Principles and Guidelines for Early Hearing Detection and Intervention Programs (2007): <http://pediatrics.aappublications.org/content/120/4/898.full>
- Footnote 10- Identification and Evaluation of Children with Autism Spectrum Disorders (2007): <http://pediatrics.aappublications.org/content/120/5/1183.full>
- Footnote 17- Immunization Schedules (2013): <http://aapredbook.aappublications.org/site/resources/IZSchedule0-6yrs.pdf>, <http://aapredbook.aappublications.org/site/resources/IZSchedule7-18yrs.pdf>, and <http://aapredbook.aappublications.org/site/resources/IZScheduleCatchup.pdf>
- Footnote 19- CDC Advisory Committee on Childhood Lead Poisoning Prevention statement "Low Level Lead Exposure Harms Children: A Renewed Call for Primary Prevention" (2012): http://www.cdc.gov/nceh/lead/ACCLPP/Final_Document_030712.pdf
- Footnote 22- AAP-endorsed guideline "Integrated Guidelines for Cardiovascular Health and Risk Reduction in Children and Adolescents" (2011): http://www.nhlbi.nih.gov/guidelines/cvd_ped/index.htm
- Footnote 25- Preventive Oral Health Intervention for Pediatricians (2008): <http://pediatrics.aappublications.org/content/122/6/1387.full> and Oral Health Risk Assessment Timing and Establishment of the Dental Home (2009): <http://pediatrics.aappublications.org/content/111/5/1113.full>. Additional information from the policies regarding fluoride supplementation and fluoride varnish has been added to the footnote.

New references were added for several footnotes, also with no change to recommendations in the Periodicity Schedule:

- Footnote 5- Expert Committee Recommendations Regarding the Prevention, Assessment, and Treatment of Child and Adolescent Overweight and Obesity: Summary Report (2007): http://pediatrics.aappublications.org/content/120/Supplement_4/S164.full
- Footnote 13- Use of Chaperones During the Physical Examination of the Pediatric Patient (2011): <http://pediatrics.aappublications.org/content/127/5/991.full>
- Footnote 15- The Recommended Uniform Newborn Screening Panel (<http://www.hrsa.gov/advisorycommittees/mchbadvisory/heritabledisorders/recommendedpanel/uniformscreeningpanel.pdf>), as determined by The Secretary's Advisory Committee on Heritable Disorders in Newborns and Children, and state newborn screening laws/regulations (<http://genes-r-us.uthscsa.edu/sites/genes-r-us/files/nbsdisorders.pdf>), establish the criteria for and coverage of newborn screening procedures and programs. Follow-up must be provided, as appropriate, by the pediatrician.

For consistency, the title of "Tuberculin Test" has been changed to "Tuberculosis Testing." The title of "Newborn Metabolic/Hemoglobin Screening" has been changed to "Newborn Blood Screening."

AAP Principles Concerning Retail-Based Clinics

POLICY STATEMENT

AAP Principles Concerning Retail-Based Clinics

abstract

FREE

The American Academy of Pediatrics views retail-based clinics (RBCs) as an inappropriate source of primary care for pediatric patients, as they fragment medical care and are detrimental to the medical home concept of longitudinal and coordinated care. This statement updates the original 2006 American Academy of Pediatrics statement on RBCs, which flatly opposed these sites as appropriate for pediatric care, discussing the shift in RBC focus and comparing attributes of RBCs with those of the pediatric medical home. *Pediatrics* 2014;133:e794–e797

INTRODUCTION

In 2006, the American Academy of Pediatrics (AAP) published its original policy statement opposing retail-based clinics (RBCs) as an appropriate source of medical care for infants, children, and adolescents and strongly discouraged their use.¹ This stance was based on the AAP commitment to the medical home model and its attributes of accessible, comprehensive, continuous, coordinated, compassionate, and culturally effective care for which the pediatrician and family share responsibility.² The structure and function of the RBC is not driven by the medical home model. The concerns expressed were based on the following attributes that influence the health care received by infants, children, and adolescents in RBCs:

- Fragmentation of care
- Possible decreased quality of care
- Provision of episodic care to children who have special needs and chronic diseases, who may not be readily identified
- Lack of access to and maintenance of a complete, accessible, central health record that contains all pertinent patient information
- Use of tests for the purpose of diagnosis without proper follow-up
- Possible public health issues that could occur when patients who have infectious diseases are in a commercial, retail environment with little or no isolation (eg, fevers, rashes, mumps, measles, strep throat)
- Seeing children who have “minor conditions,” as will often be the case in an RBC, is misleading and problematic. Many pediatricians use the opportunity of seeing the child for something minor to address other issues in the family, discuss any problems with obesity or mental health, catch up on immunizations, identify

undetected illness, and continue strengthening the relationship with the child and family. Visits for acute illnesses are important and provide an opportunity to work with patients and families to deal with a variety of other issues.

In expressing its opposition to RBCs in 2006, the AAP recognized that shifting economic and organizational dynamics of the health care system would likely support the continued existence and expansion of RBCs.¹ It outlined principles to which RBCs should be subject because of concern regarding the medical care received by pediatric patients in these settings. These principles included supporting the medical home model by referring patients back to their primary care physician or facilitating establishment of timely communication to the patient's pediatrician, using evidenced-based or evidence-informed medicine with requirements for oversight related to quality improvement, maintaining accepted protocols to manage infectious diseases, and opposing payment that offers financial incentives for use of RBCs by pediatric patients for the stated reason that the medical home is the optimal standard of care. This policy does not cover freestanding urgent care clinics, which are addressed in a separate AAP policy statement.

GROWTH, ACCEPTANCE, AND DIRECTION OF RBCs

Since the original RBC opened in 2000 in the St Paul/Minneapolis area, it is estimated that the number of RBCs has grown to more than 6000 as of 2012.^{2,3} Polls indicated that 15% of children were likely to use an RBC in the future, although the majority of patients seen in RBCs are adults.² These clinics generally follow a model of staffing by adult medicine or family practice-trained physician assistants or nurse

practitioners with off-site supervision by physician medical directors.^{4–6} Protocols are followed that dictate conditions and patients who can be seen as well as suggested treatment regimens to be followed.⁷ RBC protocols often restrict pediatric ages and conditions that will be seen by the providers. National organizations for member RBCs provide guidelines for accrediting and patient care.^{4,6}

Patients cite convenience as the most important reason for using RBCs.^{8–10} No appointment time is needed, and wait time is often minimal. Charges for minor illnesses treated are often less than a physician office and much less than an emergency department.^{11,12} Many RBCs bill insurance carriers, and some are able to bill Medicaid.⁸ Data on outcomes specifically looking at pediatric patients are limited, but minor illnesses, such as acute pharyngitis, demonstrate no significant issues with early return visits to primary care physicians.^{7,12,13}

RBCs are located in retail stores, such as grocery stores, drug stores, or “big box” stores. Average driving time for patients is less than 5 minutes, and average income and education for communities with RBCs are above average nationwide.^{5,14} More than 70% of patients report having a primary care physician. Demographic data to date do not indicate that expansion of RBCs has improved access to care in areas shown to have a shortage of primary care physicians.¹⁵

Most RBCs are owned by for-profit companies, many with a national presence.¹⁴ Most RBCs are not profitable as standalone entities and rely on location within a retail store for financial support. Some large companies have indicated plans to aggressively add RBCs to their stores and possibly expand their scope of services. Hospital and health care systems are increasingly partnering with or establishing their own RBCs

to capture or increase market share and provide other avenues of accessibility for their patients because of increasing shortages of primary care physicians in their networks and service areas.^{14,16} Insurance companies have also started expanding into opening their own full primary care centers with referral arrangements to specialists for identified problems.¹⁷

Many RBCs have protocols in place to refer patients who do not have primary care physicians or medical homes to a physician and provide correspondence of the patient's visit to those who have identified a primary care physician.

PEDIATRIC MEDICAL HOME VERSUS RBCs

A commentary published in *Pediatrics* in 2007 stressed that the emergence of RBCs has created a conflict between relative priorities of continuity of care and those of convenience and cost.¹⁸ Continuity of care embraces 3 primary dimensions: time, accessibility, and setting. Fostering a setting in which a pediatrician cares for a patient over many years (time) with knowledge of not only the medical but developmental and emotional needs of a patient and family significantly affect care and outcomes in a positive manner. Accessibility refers to ensuring care by a pediatrician and team with 24/7 availability for prompt and expert care in an appropriate medical setting. The setting is the pediatric medical home, which involves effective coordination of care throughout various medical settings, including office, hospital, home, school, and specialty referrals. The AAP, American Academy of Family Physicians, American College of Physicians, and American Osteopathic Association in 2007 issued a statement, “Joint Principles of the Patient-Centered Medical Home.” Summarized, the principles state¹⁸:

1. The patient should have an ongoing relationship with a personal physician trained to provide first contact, continuous, and comprehensive care;
2. The personal physician should lead a team of professionals who collectively take responsibility for the ongoing care of the patient;
3. The personal physician should be responsible for all aspects of the patient's care;
4. Care should be coordinated and integrated across all elements of the complex health care system; and
5. Care should be facilitated through registries, information technology, and health information exchange.

RBCs caring for children challenge this medical home concept by offering care that is arguably more convenient and less expensive but also fragmented, episodic, and not coordinated. RBC clinical providers lack pediatric training equivalent to pediatricians and do not provide after-hours coverage for patient/family questions or complications. RBCs do not typically contribute toward caring for children who cannot pay or live in underserved areas.¹⁵ As pediatric patients and their health issues become more complex, the concern exists that even a child presenting with a simple complaint may have a more serious unrecognized condition.¹⁹ In addition, there has been scope of care “creep” within the RBC setting, as these clinics now provide services such as childhood immunizations and “school and sports physicals.” These offerings impinge on core preventive care services of the pediatric medical home and are misperceived by patients and families as an appropriate substitute for regular preventive care within the medical home.

In an era of stagnant or decreasing physician payment rates by govern-

ment and private payer sources, one of the primary challenges for the primary care pediatrician is to continue to adhere to the central tenets of the medical home model by providing high-quality coordinated care in appropriate settings that optimize access, outcomes, and value. However, health care consumers, including those seeking pediatric health care services, also value convenience, a concept that, although similar, is not identical to access. Opportunities to improve convenience can include but are not limited to extended hours, open scheduling, and same-day appointments for even “minor” acute illness. Pediatricians will then have the opportunity to not only improve patient satisfaction but also increase office revenue and make the RBC setting less attractive for the care of children. At the same time, for many smaller pediatric practices, convenience can be a difficult or impossible metric with which to directly compete with RBCs without significant financial or work/life balance costs. Depending on the situation, the pediatric medical home may deem it prudent for access to incidental acute care to actively engage with RBCs within the local community as a means of expanding access without compromising the viability of the medical home and still provide an organizational plan for comprehensive care.

RECOMMENDATIONS REGARDING RBCs

1. RBCs Are an Inappropriate Source of Primary Care for Pediatric Patients

The AAP continues to oppose RBCs as a source of primary care for pediatric patients, because they risk increasing care that is fragmented and detrimental to the medical home concept of longitudinal and coordinated care.

2. Financial Payment

The AAP is opposed to payers offering lower copays or financial incentives for patients to receive care at RBCs in lieu of their pediatrician or primary care physician. Furthermore, the AAP strongly believes that the medical home is the optimal standard of care and that RBCs do not satisfy that definition. Payment for care received within the medical home must be continually evaluated to ensure that pediatricians and other primary care physicians receive adequate compensation for the continuous, coordinated, and comprehensive health care that they provide.

3. Support the Pediatric Medical Home

If pediatricians and the pediatric medical home wish to or need to use the services of an RBC within their community as a means to expand access for acute care outside of the medical home, both the medical home and the RBC should develop a formal collaborative relationship, which should include, but not be limited to:

- use of evidenced-based pediatric protocols and standards;
- pediatric quality review;
- prompt communication with the pediatric medical home of pertinent information for all visits of patients to RBCs;
- referral of all patients back to their pediatric medical home or arrangements to establish one for those who do not have one; and
- formal arrangements for after-hours coverage or emergency situations that may occur during a patient visit to an RBC.

CONCLUSIONS

The AAP continues to oppose RBCs as a source of primary care for pediatric patients. As the RBC model continues

to evolve, traditional RBCs, health systems, and insurance companies alike must recognize the critical role of the medical home in providing optimal health care for children. The AAP, its members, and the pediatric medical home should be the required partner for all RBCs that provide treatment of pediatric patients, with the pediatric medical home as the model of pediatric care.

Adolescent Pregnancy: Current Trends and Issues— Addendum

.....

- *Policy Statement*

POLICY STATEMENT

Addendum—Adolescent Pregnancy: Current Trends and Issues

INTRODUCTION

The purpose of this addendum is to update pediatricians and other professionals on recent research and data regarding adolescent sexuality, contraceptive use, and childbearing since publication of the original 2005 clinical report, "Adolescent Pregnancy: Current Trends and Issues."¹ There has been a trend of decreasing sexual activity and teen births and pregnancies since 1991, except between the years of 2005 and 2007, when there was a 5% increase in birth rates. Currently, teen birth rates in the United States are at a record low secondary to increased use of contraception at first intercourse and use of dual methods of condoms and hormonal contraception among sexually active teenagers.² Despite these data, the United States continues to lead other industrialized countries in having unacceptably high rates of adolescent pregnancy, with over 700 000 pregnancies per year, the direct health consequence of unprotected intercourse.³ Importantly, the 2006–2010 National Survey of Family Growth (NSFG) revealed that less than one-third of 15- to 19-year-old female subjects consistently used contraceptive methods at last intercourse.⁴

TRENDS IN ADOLESCENT CHILDBEARING TRENDS

Most pregnancies among adolescents in the United States are unintended (unwanted or mis-timed). In fact, 88% of births to teenagers 15 to 17 years of age were the result of unintended pregnancies.⁵ Births to 15- to 19-year-old female subjects peaked in 1991 at 61.8 per 1000 female subjects; subsequently, the rate decreased annually, except for a slight increase in 2005–2007, to reach its nadir at 39.1 per 1000 female subjects in 2011.⁶ Birth rate statistics are not the same as pregnancy rate statistics. Birth rate statistics underestimate actual adolescent pregnancy rates. The birth rate numerator includes the number of actual births per 1000 individuals in that age group, but the pregnancy rate includes actual births, abortions, and best estimates of fetal loss per 1000 adolescents in that age group.⁷

The abortion rate among adolescents 15 to 19 years of age was 14.3 per 1000 female subjects and accounted for 16.2% of all abortions in 2008.⁸ During the decade 1999 to 2008, the abortion rate decreased by 20.7% among adolescents 15 to 19 years of age, with a 5.8% decrease noted from 2004 to 2008.

SEXUAL ACTIVITY AMONG ADOLESCENTS IN THE UNITED STATES

In the 2011 Youth Risk Behavior Survey (YRBS), 47% of both female and male high school students reported “ever having had sexual intercourse.”⁹ Similar data are found in the 2006–2010 NSFG, in which the proportion of female subjects 15 to 19 years of age who ever had sexual intercourse continued to decline from 51% in 1988 to 43%.⁴ The proportion of male subjects who ever had sexual intercourse decreased from 60% to 42%.⁴ The decrease in adolescents who ever had sex was most notable in non-Hispanic black female subjects, declining from 60% to 46%, compared with Hispanic female subjects, in whom the proportion decreased from 46% to 42%. Rates of ever being sexually active among non-Hispanic black male subjects decreased from 81% to 58% and, among Hispanic male subjects, it decreased from 60% to 46%.

Most adolescents conveyed that they were “going steady” with whom they had their first sexual intercourse experience. This “going steady” relationship was reported among 70% of female subjects and 56% of male subjects. However, the earlier the age of sexual debut, the less likely the first sexual partner was a regular partner and more likely to be just a friend or someone they recently met.⁴ Furthermore, as documented in the 2002 NSFG, the majority of adolescent female subjects had a partner who was 1 to 3 years older, and those younger than 14 years were also more likely than those aged between 15 and 19 years to have partners who were 4 or more years older. This age disparity creates the potential for more non-consensual sexual encounters, increasing the risk of pregnancy and sexually transmitted diseases.¹⁰ Both the 2011 YRBS and the 2006–2010

NSFG reported that approximately one-third of adolescents (YRBS: 34% of females, 33% of males; NSFG: 31% of females, 28% of males) described having had sex with at least 1 person during the previous 3 months.^{4,9} Nearly 14% had 4 or more lifetime partners, increasing the risk of sexually transmitted diseases.^{5,9} The number of partners increases as the age at first intercourse declines.¹⁰

The 2011 YRBS data demonstrated that more 12th graders (51% female, 44% male) were sexually active than ninth graders (19% female, 24% male).⁹ Sexual activity is not always consensual, as indicated by YRBS data in which 8% of youth (11.8% of female subjects, 4.5% of male subjects) reported ever having been forced to have sexual intercourse. Unwanted first sexual encounters were reported in the NSFG among 11% of female subjects 18 to 24 years of age who had first intercourse before age 20 years.⁴ Teenagers who report first sex at 14 years of age and younger are more likely to report that it was nonvoluntary, compared with those who were aged 17 to 19 years at sexual debut.¹⁰ Unwanted encounters may include dating violence, stranger assaults, and intra-familial sexual abuse/incest. Screening for sexual violence and unwanted sexual encounters should occur during evaluation of all sexually active adolescents.

CONTRACEPTIVE USE AND EFFICACY AMONG ADOLESCENTS

It is not only the use of a contraceptive method but the type of method used that can significantly affect rates of unintended pregnancy. A study published in 2012 found that the failure rate for the short-acting methods of the contraceptive pill, patch, or ring was 4.55 per 100 participant-years compared with the long-acting reversible contraceptive methods of the implant or intrauterine device, which

had a failure rate of 0.27 per 100 participant-years.¹¹ This study also found an age differential in which women younger than 21 years were twice as likely to have an unintended pregnancy when using short-acting methods, while having the same pregnancy rates (as cited earlier) when using long-acting methods. Long-acting reversible contraception is an important contraceptive option for the adolescent that has the clear potential to reduce unintended pregnancies.

The 2006–2010 NSFG reported that only 78% of adolescent female subjects and 85% of adolescent male subjects 15 to 19 years of age used a contraceptive method for first sexual intercourse, and 86% of female subjects and 93% of male subjects used a method at last intercourse over the previous 3 months.⁴ These percentages are not significantly different compared with those from 2002. There was, however, an increase in condom use by male subjects at first intercourse as well as in dual contraceptive use (simultaneous use of condoms and hormonal contraceptives) at both first and last intercourse by female subjects.⁴

Although NSFG data revealed that the condom was the most common method used by adolescents, among 15- to 19-year-old female subjects, 56% used oral contraceptive pills, 20% used an injectable method (depot medroxy-progesterone acetate), 10% used the contraceptive patch, and 5% used the contraceptive ring. The much less reliable method of withdrawal was used by 57% of adolescent female subjects and was essentially unchanged from 2002 (55%). Emergency contraception use increased from 8% to 14% from 2002.

With respect to specific data on contraceptive use at last sexual intercourse, data from the 2006–2010 NSFG report revealed that only one-third of

15- to 19-year-old female subjects used oral contraceptive pills, 12% used other hormonal methods (depot medroxyprogesterone acetate, hormonal implant, contraceptive patch or ring, and emergency contraception), 52% used condoms, and 11% used other methods (withdrawal, sterilization, intrauterine device, female condom, diaphragm, cervical cap, spermicides [foam, jelly, cream, or suppository], sponge, or calendar/rhythm method).⁴ Similarly, the 2011 YRBS demonstrated that as few as 23% of currently sexually active female students were taking birth control pills at the time of their most recent sexual intercourse.⁹ Use of the birth control pill according to age and race/ethnicity ranged from 8% to 30% and was highest among white female subjects and 12th graders. The last time depot medroxyprogesterone acetate use was specifically reported as an individual category was in the 2009 YRBS, in which use was reported by 4% of high school female subjects, with the highest rate among black students.¹² Differential use according to race/ethnicity was also demonstrated in the 2006–2010 NSFG report, which showed that non-Hispanic black students were 3 times less likely to use oral contraceptive pills compared with non-Hispanic white students.⁴ Further information about contraception use among male subjects and gay, lesbian, bisexual, and transgender youth is available in other American Academy of Pediatrics publications.^{13,14}

Condoms

Condoms are still the most common contraceptive method used by adolescent female and male subjects according to both the YRBS and NSFG.^{4,9} Condom use remained essentially unchanged for 10th through 12th graders between 2007 and 2011 but decreased from 69% to 64% among ninth graders.⁴ Condom use at last sexual intercourse

was described by 61% of sexually active students, with a race/ethnicity breakdown of 63% of white, 62% of black, and 55% of Hispanic students. More white female (56%) students reported that their partners used condoms than Hispanic female (48.0%) students. The group with the highest rate of condom use (73%) was black male students.⁸ Similar data were found in the 2006–2010 NSFG.⁴

Pregnancy Risk Assessment Monitoring System Data

Recent data from the 2004–2008 Centers for Disease Control and Prevention (CDC) Pregnancy Risk Assessment Monitoring System describe rates of pre-pregnancy contraceptive use among 15- to 19-year-old adolescent female subjects who subsequently gave birth in 5 of 19 states that had specific data about contraceptive use.¹⁵ The findings revealed that approximately 50% of non-Hispanic white, Hispanic, and non-Hispanic black teenagers were not using contraception before becoming pregnant.

Reasons for not using contraception included not thinking they could get pregnant (31%), the partner refusing to use contraception (24%), and not being concerned about becoming pregnant (22%). All of these factors have huge implications to the pediatrician regarding the provision of anticipatory guidance and health education to adolescents in their practices.

Adolescent Pregnancy Prevention

A Cochrane Review containing 41 randomized controlled trials ranging from health education, counseling, skills-building, contraception, contraception education, and faith-based group or individual counseling (including abstinence promotion) was completed in 2009.¹⁶ It showed that a combination of educational and contraceptive

interventions lowered the rate of unintended pregnancy among adolescents. However, on the basis of this review, there was no conclusive evidence that any specific intervention program had effects on initiation of sexual intercourse, use of birth control methods, or abortion.

In fiscal year 2010 appropriations, Congress funded the President's new Teen Pregnancy Prevention Initiative. Of the funds made available, \$75 million funded the replication of medically accurate and age-appropriate programs that reduce teen pregnancy, and \$25 million was allocated to develop and test additional models and innovative strategies.¹⁵ As part of this effort, the CDC is supporting a 5-year (2010–2015) multicomponent demonstration project to reduce the rates of pregnancies and births to youth by 10% in targeted communities. These demonstration projects are designed to increase linkage between teen pregnancy prevention programs and community-based clinical services, increase youth access to teen pregnancy prevention programs that are evidence based and/or evidence informed, and educate stakeholders about relevant evidence-based and evidence-informed strategies to reduce teen pregnancy. The needs and resources in the targeted communities are also identified.¹⁷

CONCLUSIONS

Although there are decreasing numbers of teenagers who become pregnant, the issue remains an important concern, particularly because the United States still has among the highest teen pregnancy rates in the industrialized world. Fortunately, there are many tools available to combat teen pregnancy, and the CDC effort is one example of renewed interest and distribution of resources for this important issue.

abstract

FREE

The number of anterior cruciate ligament (ACL) injuries reported in athletes younger than 18 years has increased over the past 2 decades. Reasons for the increasing ACL injury rate include the growing number of children and adolescents participating in organized sports, intensive sports training at an earlier age, and greater rate of diagnosis because of increased awareness and greater use of advanced medical imaging. ACL injury rates are low in young children and increase sharply during puberty, especially for girls, who have higher rates of noncontact ACL injuries than boys do in similar sports. Intrinsic risk factors for ACL injury include higher BMI, subtalar joint overpronation, generalized ligamentous laxity, and decreased neuromuscular control of knee motion. ACL injuries often require surgery and/or many months of rehabilitation and substantial time lost from school and sports participation. Unfortunately, regardless of treatment, athletes with ACL injuries are up to 10 times more likely to develop degenerative arthritis of the knee. Safe and effective surgical techniques for children and adolescents continue to evolve. Neuromuscular training can reduce risk of ACL injury in adolescent girls. This report outlines the current state of knowledge on epidemiology, diagnosis, treatment, and prevention of ACL injuries in children and adolescents. *Pediatrics* 2014;133:e1437–e1450

INTRODUCTION

Anterior cruciate ligament (ACL) injuries are a serious concern for physically active children and adolescents. The ACL is 1 of the 4 major ligaments that stabilize the knee joint (Fig 1). Its main function is to prevent the tibia from sliding forward relative to the femur. The ACL also assists with preventing excessive knee extension, knee varus and valgus movements, and tibial rotation.^{1,2} An intact ACL protects the menisci from shearing forces that occur during athletic maneuvers, such as landing from a jump, pivoting, or decelerating from a run.

Physicians caring for young athletes have noted an increase in the numbers of ACL injuries over the past 2 decades.^{3,4} Reasons for the increase in ACL injury rate include the growing number of children and adolescents participating in organized sports, increased participation in high-demand sports at an earlier age, and a greater rate of diagnosis as a result of increased awareness that ACL injuries can occur in skeletally immature patients and more frequent use of advanced medical imaging.^{4–8}

EPIDEMIOLOGY OF ACL INJURY

The incidence of ACL injuries in the general population can be estimated from national registries, which were established in Norway (2004), Denmark (2005), and Sweden (2006) to monitor the outcomes of ACL reconstruction surgery. Between 2006 and 2009, all Norwegian hospitals participated in the registry, with a total compliance of 97%. In the 10- to 19-year age group, the annual incidence of primary ACL reconstructions was 76 per 100 000 girls and 47 per 100 000 boys.⁹ This number underestimates the true incidence of ACL injuries, however, because it does not include those treated nonoperatively.

Most ACL injuries are sports-related; therefore, injury rates are higher in athletes. The National Collegiate Athletic Association Injury Surveillance System has compiled data for 16 sports (8 men's and 8 women's) over 16 years from a sample of colleges and universities (approximately 15%).² ACL injury rates were highest in men's spring football and women's gymnastics (33

per 100 000 athlete-exposures) (Fig 2). In women's sports, ACL injury rates represented a larger proportion of total injuries than in men's sports (3.1% vs 1.9%), with women's basketball and women's gymnastics topping the list at 4.9% of total injuries.¹⁰

Overall, high school athletes have lower rates of ACL injuries than do collegiate athletes (5.5 vs 15 per 100 000 athlete-exposures) but a similar injury distribution across sports.^{2,11} Since 2005, the National High School Sports-Related Injury Surveillance Study has compiled data on the incidence of ACL injuries in 18 sports.¹¹ From 2007 to 2012, ACL injury rates were highest in girls' soccer and boys' football (11.7 and 11.4 per 100 000 athlete-exposures, respectively) (Fig 3).

No well-designed epidemiologic studies to document ACL injury rates have been conducted in children younger than 14 years. Although there have been reports of sport-related ACL injuries in children as young as 5 years, the limited data available suggest that ACL disruptions in children younger than 12 years are rare.^{12–16} McCarroll et al¹⁶ found that of the 1722 ACL injuries diagnosed over

a 6-year period at their sports medicine center, 57 (3%) were in children 14 years and younger. The Norwegian ACL Surgical Registry collects data for all ACL surgeries performed at participating institutions nationwide. From 2004 to 2011, this registry recorded a total of only 8 to 9 ACL surgeries each year for children 11 to 13 years of age. This represents a small fraction (0.6%) of the total number of ACL surgeries recorded each year (1441) in this registry across all age groups. For the children who had surgery, the age at the time of injury ranged from 9 to 13 years.

The ACL surgery rate for 12- to 13-year-olds (3.5 per 100 000 citizens) was substantially lower than that for 16- to 39-year-olds (85 surgeries per 100 000 citizens), the age group at highest risk.⁹ Again, these numbers underestimate the actual injury rates, because they do not account for those treated nonoperatively.

Gender Differences

ACL injury risk begins to increase significantly at 12 to 13 years of age in girls and at 14 to 15 years of age in boys.^{9,12} Female athletes between 15 and 20

FIGURE 2

years of age account for the largest numbers of ACL injuries reported (Fig 4). The gender disparity in ACL injury rates among athletes begins to appear around the time of the growth spurt (12–14 years of age for girls and 14–16 years of age for boys), peaks during adolescence, then declines in early adulthood.^{10,12} At the high school level, ACL injury rates in gender-comparable sports (soccer, basketball, baseball/softball, track, volleyball) are

2.5 to 6.2 times higher in girls compared with boys.^{10,11,17} In college athletics, ACL injury rates are 2.4 to 4.1 times higher for women, and at the professional level, ACL injury rates for men and women are essentially equal.^{4,10,18} In high school sports, ACL injuries represent a higher proportion of all injuries in female versus male athletes (4.6% vs 2.5%), with girls' basketball topping the list (6%), followed by girls' soccer, girls' gymnastics, and girls'

FIGURE 4

volleyball (each 5%). Compared with boys, girls are more likely to have surgery and less likely to return to sports after an ACL injury.^{17,19} Among female high school basketball players, knee injuries were the most common cause of permanent disability, accounting for up to 91% of season-ending injuries and 94% of injuries requiring surgery.^{20,21}

CONSEQUENCES OF ACL INJURY

An ACL injury at an early age is a life-changing event. In addition to surgery and many months of rehabilitation, the treatment costs can be substantial (\$17 000–\$25 000 per injury), and the time lost from school and sports participation can have considerable effects on the athlete's mental health and academic performance.^{22,23} Although ACL injuries account for approximately 3% of all injuries in college sports, they account for 88% of injuries associated with 10 or more days of time lost from sports participation. Freedman et al²⁴ examined the academic transcripts of college students who underwent ACL reconstruction surgery. Compared with an age-matched control group, those who had surgery had a significant drop in grade point average of 0.3 points during the semester of injury ($P = .04$). Similarly, Trentacosta et al²⁵ found that athletes 18 years and younger who had ACL reconstruction surgery during the school year reported that it had a negative effect on their grades.

Beyond these more immediate effects, an ACL injury also has long-term health consequences. Regardless of the type of treatment, athletes with ACL injury are up to 10 times more likely to develop early-onset degenerative knee osteoarthritis, a condition that not only limits one's ability to participate in sports but also often leads to chronic pain and disability.^{26,27} A systematic review of a series of long-term studies suggests the rates of degenerative

knee osteoarthritis 10 to 20 years after ACL injury are more than 50%.²⁷ This means children and teenagers who suffer ACL injuries are likely to face chronic pain and functional limitations from knee osteoarthritis in their 20s and 30s. None of these studies, however, demonstrated that ACL reconstruction lowered the risk for osteoarthritis. In fact, one 5-year prospective study showed that patients who had ACL reconstruction had a higher level of knee arthrosis on radiographs and bone scans, compared with patients who did not undergo ACL reconstruction.²⁸

INJURY MECHANISMS

The mechanism of ACL injuries in athletes is likely multifactorial. Proposed theories to explain the mechanisms underlying ACL injury include extrinsic (physical and visual perturbations, bracing, and shoe-surface interaction) and intrinsic (anatomic, hormonal, neuromuscular, and biomechanical) variables. Identification of extrinsic and intrinsic risk factors associated with the ACL injury mechanism provides direction for targeted interventions to high-risk individuals.

At least 70% of ACL injuries are non-contact in nature^{29,30}; however, the specific definition of a noncontact ACL injury varies from study to study. Some define a noncontact ACL injury as one that occurs in the absence of a player-to-player (body-to-body) contact. Others define noncontact ACL injury as one that occurs in the absence of a direct blow to the knee. An ACL injury resulting from body-to-body contact but with no direct blow to the knee may be classified as “noncontact ACL injury with perturbation.”

Video analysis of ACL injury during competitive sports play indicates a common body position associated with noncontact ACL injury (Fig 5) in which (1) the hip is internally rotated,

(2) the knee is close to full extension, (3) the foot is planted, and (4) the body is decelerating, leading to apparent valgus collapse of the knee or “dynamic knee valgus.”^{31–33} ACL injury is also observed to occur when the body's center of mass is behind and away from the base of support or the area of foot-to-ground contact.³¹

RISK FACTORS

ACL injury risk in young athletes is likely multifactorial. Injury data from many fields demonstrate that numerous physical and psychological parameters affect ACL injury rates.

Genetics

Genetic factors likely play a role, although the genetic underpinnings of increased ACL injury risk have only recently begun to be examined.³⁴

Hormones

Hormonal factors also likely play a role; however, results of studies investigating hormonal factors are both equivocal and controversial.³⁵ Although the female knee appears to get slightly more lax, on the order of 0.5 mm, at midmenstrual cycle, injuries tend to cluster near the start of menses at the polar opposite time in the cycle.^{36,37}

Previous Injury

Similar to other musculoskeletal injuries, one of the single best predictors of future ACL injury is previous ACL injury. One study found the incidence rate of ACL injury in athletes who have had ACL reconstruction was 15 times greater than that of control subjects.³⁸ Female athletes were 4 times more likely to suffer a second ACL injury in either knee and 6 times

FIGURE 5

Dynamic knee valgus: hips are internally rotated and adducted, tibiae are externally rotated, and feet are everted.

more likely to suffer a new ACL injury in the contralateral knee than male athletes. In fact, subsequent injuries to the contralateral ACL are twice as common as reinjury of the reconstructed ACL (11.8% vs 5.8%).³⁹ Genetic, anatomic, and neuromuscular factors likely play a role.

Age and Gender

Although ACL injury rates increase with age in both genders, girls have higher rates immediately after the growth spurt.^{9–12,16} It is likely that the increases in body weight, height, and bone length during pubertal development underlie the mechanism of increased risk of ACL injury with increasing age. During puberty, the tibia and femur grow at a rapid rate.⁴⁰ This growth of the 2 longest levers in the human body translates into greater torques on the knee.⁴¹ Increasing height leads to a higher center of mass, making muscular control of this center of mass more challenging. Increasing body weight is associated with greater joint force that is more difficult to balance and dampen during high-velocity athletic movements. In pubertal boys, testosterone mediates significant increases in muscular power, strength, and coordination, which affords them with greater neuromuscular control of these larger body dimensions. Pubertal girls do not experience this same growth spurt in muscular power, strength, and coordination, which likely explains their higher rates of ACL injuries compared with pubertal boys.⁴¹ That preadolescent athletes show no gender differences in ACL injury rates further supports this theory.¹²

Anatomic/Anthropometric Factors

Greater weight and BMI have been associated with increased risk of ACL injury.^{31,42} A study of military recruits found that body weight or BMI >1 SD above the mean was associated with

a 3.2 and 3.5 times greater risk of ACL injury, respectively.⁴² In a study of female soccer players older than 8 years, BMI was a significant risk factor for knee injury.³¹

An increased quadriceps angle (Q angle) has been postulated as a risk factor, but there have been no prospective clinical studies to investigate the relationship between Q angle and ACL injury risk.^{43–45} A narrow intercondylar notch, where the ACL is housed, is proposed to increase ACL injury risk, because a narrow notch tends to be associated with a smaller, weaker ACL and also could cause increased elongation of the ACL under high tension.^{46,47} Some studies have shown that a narrow notch increases risk of ACL injury^{42,47,48}; however, others have shown no association between notch width and ACL injury.^{18,49,50} Subtalar joint overpronation has been associated with noncontact ACL injuries,⁵¹ likely because overpronation increases anterior translation of the tibia with respect to the femur, thereby increasing the strain on the ACL.⁵²

Generalized joint laxity and knee hyperextension were found to significantly increase the risk for ACL injury in female soccer players.⁵³ Patients with ACL injury have significantly more knee recurvatum at 10 and 90 degrees of hip flexion and an increased ability to touch palms to floor.²⁹ Athletes with generalized joint laxity had a 2.7 times greater risk of ACL injury than did those without generalized laxity, and those with increased anterior-posterior laxity of the knee, as measured by a knee arthrometer, had an approximately 3 times greater risk of ACL injury than did those without such laxity.⁴² Joint laxity affects not only sagittal knee motion (hyperextension) but also coronal knee motion (valgus), which can strain the ACL and be related to increased risk in athletes.^{29,42,54}

Neuromuscular Factors

Muscle strength and coordination have a direct effect on the mechanical loading of the ACL during sport movements.^{55,56} Poor neuromuscular control of the hip and knee and postural stability deficits have been shown to be risk factors for ACL injury.^{54,57} Landing and pivoting sports involve a great deal of rapid deceleration and acceleration movements that push and pull the tibia anteriorly and place the ACL under stress. This tibial translation can be modulated by hamstrings and quadriceps activity.^{58,59} In vivo studies show when subjects were asked to contract their muscles, knee laxity is reduced by 50% to 75%.⁵⁸ Activation of the quadriceps before the hamstrings, a pattern more frequently seen in female individuals, increases the anterior shear force that directly loads the ACL and also could be related to increased dynamic valgus alignment at initial contact during cutting and landing maneuvers.^{41,60–65} Although fatigue is often cited as a potential risk factor for ACL injury, there are relatively few published studies to support or refute this.⁶⁶

MAKING THE DIAGNOSIS

History

The patient with an acute ACL tear typically presents with pain, a knee effusion, a reduction in knee motion, and difficulty bearing weight. Often a “pop” is heard or felt by the athlete at the time of injury. The prevalence of an ACL tear in a pediatric athlete with a traumatic knee hemarthrosis is about 65%.⁶⁷ The patient with a chronic ACL tear typically presents with recurrent effusions and the sense that the knee “gives way” or is unstable with attempts at cutting, twisting, or jumping sports.

Physical Examination

In a pediatric athlete with an acute traumatic knee effusion, the Lachman test, anterior drawer test, and pivot

shift test are clinical examinations that aid in making the diagnosis of an ACL tear.

The Lachman test is performed with the patient supine (Fig 6). The injured knee is flexed to 30 degrees. The examiner places 1 hand behind the tibia with the examiner's thumb on the tibial tubercle and the other hand on the patient's lower thigh. The tibia is pulled anteriorly. Examinations of both knees are compared. Increased anterior movement of the tibia relative to the femur without a firm end point compared with the examination of the uninjured knee suggests a torn ACL.

The anterior drawer test also is performed with the patient supine but with the knee flexed to 90 degrees (Fig 7). The examiner grasps the tibia just below the knee joint, with the examiner's thumbs placed on either side of the patellar tendon. The tibia is pulled forward. An increased amount of anterior tibial translation compared with the opposite leg or a lack of a firm end point suggests a torn ACL.⁶⁹ Both the Lachman and anterior drawer tests require a relaxed patient without hamstring guarding.

The pivot shift test is performed with the patient supine and the knee extended (Fig 8). The examiner stresses

the lateral side of the knee while gradually flexing the patient's knee. A "clunk" sensation occurs when the partly subluxated tibia relocates in relation to the femur, indicating that the ACL is torn. The pivot shift test is often difficult to perform in the pediatric athlete with an acute knee injury because of pain and guarding.

The Lachman test is considered the most accurate of the 3 commonly performed clinical tests for an acute ACL tear, showing a pooled sensitivity of 85% (95% confidence interval [CI] 83–87) and a pooled specificity of 94% (95% CI 92–95). The pivot shift test is very specific, namely 98% (95% CI 96–99), but has a poor sensitivity of 24% (95% CI 21–27).^{68,69} Last, the knee arthrometer is an objective, accurate, and validated tool that measures, in millimeters, the amount of tibial translation relative to the femur while performing a Lachman test and, thus, augments the clinical examination when examining a patient with an ACL tear.^{70,71}

Imaging

For the pediatric athlete who presents with a traumatic knee effusion, plain radiographs should be obtained to rule out fracture, dislocation, osteochondral

injury, or physeal injury in addition to, or instead of, an ACL tear. MRI is usually not necessary to make the diagnosis of an ACL tear, as a positive Lachman test result is sufficient. However, in the pediatric patient whose physical examination is difficult to perform because of pain, swelling, and/or lack of cooperation or if there is concern for associated injuries or subtle physeal fracture, MRI may be a valuable ancillary tool.^{72–76} MRI also can be useful for surgical planning. Sensitivity and specificity of MRI for detecting ACL tears in children has been reported to be 95% and 88%, respectively.⁷⁶ For meniscal tears in children, MRI has been reported to be 100% sensitive and 89% specific.⁷² One study found that the sensitivity, specificity, positive predictive value, and accuracy of MRI for identifying all categories of pathologic changes were lower for pediatric (ages 4–14 years) versus adolescent (ages 15–17 years) patients.⁷⁵

TREATMENT

The treatment of ACL tears in the pediatric athlete is challenging and controversial. An ACL tear in a child is not a surgical emergency. Multiple timely discussions with the parents and the child about the appropriate management options and understanding their goals and expectations are very important.⁷³ Surgery is not absolute. The general indications for surgery include the patient's inability to participate in his or her chosen sport, instability that affects activities of daily living, and an associated repairable meniscal tear or a knee injury with multiple torn ligaments. Treatment of ACL injuries in the skeletally immature patient remains controversial, because standard ACL reconstructions involve the use of drill holes that cross the open physes and may potentially cause growth disturbance, such as shortening or angulation of the child's leg.⁸ A meta-analysis of 55

studies suggested that the risk of leg length difference or angular leg deviations was approximately 2% after ACL reconstruction in children and adolescents.⁷⁷ The authors recommended randomized controlled trials to clarify this risk more accurately. Ideally, surgical treatment of an ACL tear in a skeletally immature athlete would be postponed until skeletal maturity, and

the athlete would not develop meniscal tears during that waiting time. In the past, delay in surgical treatment was very common. Orthopedic surgeons recommended nonoperative treatment, including a brace, rehabilitation, and sports restriction for many months until skeletal maturity occurred and traditional ACL surgery could be performed safely.^{73,78,79} For some pediatric

athletes and parents, conservative management still may be a reasonable treatment option. However, many pediatric athletes and their parents are less inclined to agree to restrict the athlete's activity. In such cases, an ACL tear in the pediatric athlete treated conservatively can lead to additional instability episodes, meniscal tears, articular cartilage damage, and early-onset arthritis.^{80–84} Therefore, most recent literature now supports early surgery for pediatric athletes with an ACL-deficient knee and recurrent episodes of instability.^{82,85–87} Overall, ACL surgery is about 90% successful in restoring knee stability and patient satisfaction.⁸⁸

No consensus exists on the best method to treat an ACL tear in a pediatric athlete. Safe and effective surgical techniques continue to evolve.⁷⁸ However, the current literature suggests reasonable, evidenced-based management options that minimize the risks of iatrogenic growth plate injury.⁸⁹ For example, ACL surgery in a pediatric athlete is often performed via a physeal-sparing technique or a transphyseal technique.^{86,90–92} The physeal-sparing technique avoids injury to the growth plate, but it places the graft in a nonanatomic position. An accurate understanding of the athlete's physical maturity by determining skeletal age and Tanner stage helps to identify which treatment is best for a specific patient.^{73,86,87,92–98} The most common method of measuring the patient's skeletal age is to compare an anteroposterior radiograph of the patient's left hand and wrist to an age-specific radiograph in the Greulich and Pyle atlas.⁹⁴ Tanner stage can be determined by self-assessment, which has been shown to be valid and reliable.⁹⁹

Patients with open physes at Tanner stage III and skeletal age of less than 14 in girls and less than 16 in boys can be offered the option of activity modification, functional bracing, rehabilitation, and careful follow-up. Surgery is

indicated in skeletally immature patients with a torn ACL and an additional repairable meniscal injury and in patients who failed conservative care. In addition, ACL surgery can be elected by patients unwilling to comply with activity restrictions and bracing. Parents and patients who request surgery before maturation of the growth plates should be counseled about the risk of angular or longitudinal growth injury and the possible need for additional surgery.^{16,100–103}

Most orthopedic surgeons select a surgical treatment option based on the patient's skeletal and physiologic age. For example, in the high-risk, most skeletally immature athlete (skeletal age less than 11 in girls and less than 13 in boys, and Tanner stage I or II) an extraphyseal procedure using a band of the iliotibial tendon or a hamstring tendon graft passed over the top of the lateral femoral condyle and through a groove in the anterior tibia is a reasonable surgical option.^{15,103–106} Both of these extraphyseal procedures avoid the growth plate to prevent the risk of growth disturbance. A third option for the completely immature pediatric athlete is a more technically demanding all-epiphyseal procedure using hamstring tendon grafts. Some authors have used intraoperative 3-dimensional computed tomography to confirm the precise tunnel location and minimize risk of physeal injury.⁸⁹

In the intermediate-risk mid-age child (skeletal age 11 to 14 in girls and 13 to 16 in boys, and Tanner stage III or IV), the previous physeal-sparing methods may be selected; however, many of these intermediate-maturity patients are safely and more appropriately treated with transphyseal reconstruction using small 7- to 8-mm centrally placed drill holes and a soft tissue graft, such as the hamstring tendons or an allograft.^{106–109} Physeal injury can be minimized by us-

ing a small drill hole and soft tissue grafts and by placing the fixation away from the physis. Patients and parents should be counseled that there remains a small risk of physeal injury and a possibility of additional surgery for angular or growth disturbance.

Last, adolescents who are approaching skeletal maturity (skeletal age older than 14 in girls and older than 16 in boys, Tanner stage V) can undergo anatomic ACL surgery with tibial and femoral drill holes and the surgeon's graft of choice with minimal risk of physeal injury.^{82,110,111} Autografts and allografts are both reasonable graft choices depending on the patient and surgeon preferences. Autografts have a lower graft failure rate in 2 studies.^{112,113}

Rehabilitation after ACL surgery may need to be modified for the individual patient and the particular surgical procedure. In general, a graduated rehabilitation program emphasizing full extension; immediate weight bearing; active range of motion; and strengthening of the quadriceps, hamstrings, hip, and core can be started in the first few weeks after surgery. Progressive rehabilitation during the first 3 months after surgery includes range-of-motion exercises, patellar mobilization, proprioceptive exercises, endurance training, and closed-chain strengthening exercises. Straight-line jogging, plyometric exercises, and sport-specific exercises are added after 4 to 6 months. Return to play typically occurs 7 to 9 months after surgery.

Return to Sport

Studies of competitive athletes, most of whom were older than 18 years, in a variety of sports have demonstrated that 78% to 91% returned to sports participation after ACL reconstruction.¹¹⁴ However, only 44% to 62% returned to their previous level of athletic performance.^{114–119} Female athletes were less likely than male

athletes to return to sports after ACL injury or ACL reconstruction.^{19,119,120}

ACL INJURY PREVENTION

Bracing

It is unlikely that prophylactic bracing can decrease the risk of ACL injury. The relative effects of 6 different brace designs on anterior tibial translation and neuromuscular function were studied in chronically unstable ACL-deficient patients.¹²¹ Bracing decreased anterior tibial translation in the range of 30% to 40% without the stabilizing contractions of the hamstrings, quadriceps, or gastrocnemius muscles. With muscle activation and bracing, anterior tibial translation was decreased between 70% and 85%. However, the braces slowed hamstring muscle reaction times. A brace with a 5-degree extension stop decreased extension on landing.¹²²

Functional bracing after ACL reconstruction has been studied using randomized controlled cohorts placed into braced or nonbraced groups.¹²³ The braced group was instructed to wear a functional knee brace for all cutting, pivoting, or jumping activities for the first year after ACL reconstruction. There were no differences between groups in knee stability, functional testing, subjective knee scores, and range of motion or strength testing, and the investigators concluded that postoperative bracing did not change outcomes. Data are insufficient at this time to determine whether functional bracing decreases the risk of ACL injury or reinjury. Knee bracing does not improve functional performance of subjects after ACL reconstruction and may actually reduce running and turning speed.¹²⁴

Neuromuscular Training Programs

Although ACL injuries occur too quickly for reflexive muscular activation,

athletes can adopt or “preprogram” safer movement patterns that reduce injury risk during landing, pivoting, or unexpected loads or perturbations during sports movements.^{54,60} With sufficient neuromuscular control of knee position to avoid dynamic valgus, knee stability may be improved during competitive sport and the risk of ACL injury can be significantly reduced. A collection of prospective cohort studies and randomized controlled trials have examined the effect of neuromuscular training programs on ACL, knee, and other lower-extremity injuries in soccer, basketball, volleyball, and handball (Fig 9).^{22,125–137} Some studies used only 1 or 2 types of exercises, such as plyometric exercises and/or balance exercises, and others applied a more comprehensive approach by including plyometrics (repetitive jumping exercises designed to build lower-extremity strength and power), strengthening, stretching, and balance training.

Systematic examination of the data extracted from these studies leads to a few potentially valuable generalizations.^{138–140} Plyometric training combined with technique training and feedback to athletes regarding proper form were the common components of programs that effectively reduced ACL injury rates. Balance training alone may not be sufficient to reduce ACL injury risk. Although some of the effective programs did not include strength training, those that did were among the most effective at decreasing ACL injury rates. ACL injury reduction was greatest for soccer athletes, and combined pre- and in-season training was more effective than pre- or in-season training alone. With respect to age, the greatest reduction in injury risk was demonstrated for female athletes in their mid-teens (14–18 years) compared with those in their late teens (18–20 years) and adults (>20 years), with 72% risk reduction for those <18 years of age

and 16% risk reduction for those ≥18 years of age. This suggests the best window of opportunity for ACL injury risk reduction may be during early pubertal maturation, at or just before girls’ neuromuscular risk factors start to become evident and ACL injury rates in girls dramatically increase. It is unknown whether neuromuscular training or other interventions can modulate the increased risk of early-onset degenerative knee arthritis after ACL injury.¹⁴¹

More information about specific evidence-based neuromuscular training programs can be found in the respective articles describing their study results.^{125–137} In addition, the AAP has compiled a series of evidence-based resources that include instructional videos for pediatricians, athletes, and coaches who would like to learn more about neuromuscular training and how to perform the preventive exercises (<http://www.aap.org/cosmf>).

CONCLUSIONS AND GUIDANCE FOR CLINICIANS

1. The number of ACL injuries in young athletes has increased over the past 2 decades, coincident with the growing number of children and adolescents participating in or-

ganized sports, intensive sports training at an earlier age, and greater rate of diagnosis because of increased awareness and greater use of advanced medical imaging.

2. Intrinsic risk factors for ACL injury include higher BMI, subtalar joint overpronation, generalized ligamentous laxity, and decreased neuromuscular control of the trunk and lower extremities.
3. ACL injury rates are low in young children and increase sharply during puberty, especially for girls, who have higher rates of ACL injuries than boys do in similar sports.
4. Although there likely are multiple factors underlying the differences in noncontact ACL injury rates in male and female athletes, neuromuscular control may be the most important and most modifiable factor.
5. ACL injuries often require surgery and/or many months of rehabilitation and substantial time lost from school and sports participation.
6. The best physical examination test for an ACL tear is the Lachman test.
7. MRI can be valuable for diagnosing ACL tears and associated meniscal and chondral injury in

FIGURE 9

Reduction of noncontact ACL injury with neuromuscular training. (Reproduced with permission from Myer GD, Sugimoto D, Thomas S, Hewett TE. The influence of age on the effectiveness of neuromuscular training to reduce anterior cruciate ligament injury in female athletes: a meta-analysis. *Am J Sports Med*. 2013;41(1):209.¹³⁸)

the pediatric athlete whose physical examination is difficult to perform because of pain, swelling, and lack of cooperation.

8. An ACL tear in a youth athlete is not a surgical emergency. Multiple discussions with the athlete and parents may be needed to understand the athlete's goals and parental expectations and to educate the family about possible treatment options.
9. The patient's skeletal age, measured by an anteroposterior radiograph of the left hand and wrist, and Tanner stage are helpful for the physician in deciding the most appropriate treatment of an ACL tear in a skeletally immature athlete.
10. Pediatricians and orthopedic surgeons treating young people with ACL injuries should advise them that regardless of treatment choice, they are at increased risk of early-onset osteoarthritis in the injured knee. Such discussions should be appropriately documented in the patient's medical record.
11. Musculoskeletal changes that decrease dynamic joint stability in high-risk female athletes and potentially lead to higher injury rates in this population could be modified if neuromuscular training interventions are instituted in early-middle adolescence, when the neuromuscular risk factors for ACL injury start to develop.
12. Neuromuscular training appears to reduce the risk of injury in adoles-

cent female athletes by 72%. Prevention training that incorporates plyometric and strengthening exercises, combined with feedback to athletes on proper technique, appears to be most effective.

13. Pediatricians and orthopedic surgeons should direct patients at highest risk of ACL injuries (eg, adolescent female athletes, patients with previous ACL injury, generalized ligamentous laxity, or family history of ACL injury) to appropriate resources to reduce their injury risk (<http://www.aap.org/cosmf>). Such discussions also should be appropriately documented in the patient's medical record.
14. Pediatricians and orthopedic surgeons who work with schools and sports organizations are encouraged to educate athletes, parents, coaches, and sports administrators about the benefits of neuromuscular training in reducing ACL injuries and direct them to appropriate resources (<http://www.aap.org/cosmf>).

POLICY STATEMENT

Application of the Resource-Based Relative Value Scale System to Pediatrics

abstract

FREE

The majority of public and private payers in the United States currently use the Medicare Resource-Based Relative Value Scale as the basis for physician payment. Many large group and academic practices have adopted this objective system of physician work to benchmark physician productivity, including using it, wholly or in part, to determine compensation. The Resource-Based Relative Value Scale survey instrument, used to value physician services, was designed primarily for procedural services, leading to current concerns that American Medical Association/Specialty Society Relative Value Scale Update Committee (RUC) surveys may undervalue nonprocedural evaluation and management services. The American Academy of Pediatrics is represented on the RUC, the committee charged with maintaining accurate physician work values across specialties and age groups. The Academy, working closely with other primary care and subspecialty societies, actively pursues a balanced RUC membership and a survey instrument that will ensure appropriate work relative value unit assignments, thereby allowing pediatricians to receive appropriate payment for their services relative to other services. *Pediatrics* 2014;133:1158–1162

BACKGROUND

Creation of Resource-Based Relative Value Scale Payment System

The Medicare Resource-Based Relative Value Scale (RBRVS) was legislated by the Omnibus Budget Reconciliation Act of 1989. The RBRVS-based physician payment system relies on¹ objective measures of physician work, termed work relative value units (wRVUs)²; assessments of the practice expense in providing professional services to patients; and³ the professional liability insurance expense inherent in each specific service. These 3 components are then corrected for geographic variations in salaries and the cost of goods and services. In this way, the RBRVS system has eliminated many of the dramatic disparities that existed when payments were based on the customary, prevailing, and reasonable fees for the service provided.

Conversion Factor

The RBRVS mandate was accompanied by a legislative requirement for annual Medicare budget neutrality. To accomplish this, Congress established the annually updated conversion factor (CF); the dollar

amount Medicare will pay for each relative value unit (RVU) of service (total RVU $\times$ CF = payment). By legislation, annual increases for new technology or treatments were restricted to \$20 million annually. Congress provided for an annual update to the CF based on the percentage increase in the Medicare Economic Index. This index is a comparison of the projected increases in use, described as the Medicare Volume Performance Standard, to the actual increase in spending and other Medicare funding factors. Inability to control this growth in physician services led to the Balanced Budget Act of 1997, which replaced the Medicare Volume Performance Standard with the sustainable growth rate (SGR) system now used to control Medicare expenditures.

Sustainable Growth Rate

The SGR is a complex formula used to determine the annual CF on the basis of the projected growth in per capita gross domestic product. Higher-than-projected use of services results in a reduction to the following year's CF. Expected reductions in the Medicare CF over previous years (eg, -20.1% for 2014) have only been avoided by last-minute congressional legislative action. The Patient Protection and Affordable Care Act (ACA) of 2010 replaces the unworkable SGR formula with one that is more closely tied to inflation and the Medicare Economic Index. The ACA also establishes a public/private committee to recommend the level of annual increase in CF. Recent bipartisan Congressional bills would replace the SGR but freeze Medicare payments for 10 years. The AAP strongly endorses this replacement but will also insist that this freeze not delay continued efforts to attain cognitive and non-face-to-face care parity with procedural services.

The American Academy of Pediatrics (AAP) supports the replacement of the

SGR formula with one that more closely ties physician payment to inflation and the medical economic index, similar to that proposed in the ACA.

Five-Year Review Process

At RBRVS's inception, Congress also mandated a 5-year review of work values to review changes in medical practice that might increase or decrease the cost of providing specific services or to revisit perceived inequities in RBRVS values. For example, as part of the 2010 5-year review, preventive medicine services codes were resurveyed on the basis of updated *Bright Futures* care recommendations, resulting in increased wRVUs for those services.

Pediatric Current Procedural Terminology Codes

The AAP Committee on Coding and Nomenclature has sought and continues to seek input from AAP sections, councils, and committees regarding the development of new/revised *Current Procedural Terminology* (CPT) codes that reflect changes in the provision of services to children. New CPT codes or revisions to existing CPT codes can be proposed by any individual or entity, but those sponsored by medical specialty societies are considered more representative of current medical practice. Once a new/revised CPT code is accepted by the CPT Editorial Panel, the AAP Committee on Coding and Nomenclature then works within the American Medical Association/Specialty Society Relative Value Scale Update Committee (RUC) process to provide the Centers for Medicare and Medicaid Services (CMS) with wRVU and direct practice expense recommendations that accurately reflect the resources expended in providing those services to children. Each November, the CMS publishes (in the *Federal Register*) the upcoming year's RBRVS fee schedule for public

comment. In some cases, the CMS accepts the RUC recommended values. However, in other cases, the CMS has published values that have differed from those recommended by the RUC and, as such, the AAP has been very active in its advocacy efforts to reverse those CMS decisions when they have adversely affected payment for services that are critically important to children or recommended by established guidelines, such as those contained in *Bright Futures*.

Non-Medicare Use of RBRVS

Payers are required to use CPT as the procedural code set, as defined by the Health Insurance Portability and Accountability Act of 1996 (HIPAA). The majority of non-Medicare payers, including state Medicaid programs and commercial insurers, use the Medicare RBRVS payment system to set payment for CPT codes. According to an American Medical Association (AMA) survey of 127 different public and private payers, 77% of respondents use the Medicare RBRVS.¹ However, non-Medicare payers are not legally bound to use the Medicare RBRVS (or its CF) and can establish their own payment methodologies. The AAP private payer advocacy initiative is constantly working with insurers to make certain that payment policies are RBRVS-based and meet the needs of children and their health care providers.

The Medical Home

Both the Medicare program and the enacted ACA are focused on enhancing the quality of services provided to enrollees while controlling non-value-added use of services through an increased emphasis on prevention and chronic disease management. Patient education, medication management, preventive screening, chronic disease case management, and telephone/

electronic patient communication are critical to the success of the medical home model. The AAP is working with other primary care specialties to develop codes and obtain RBRVS valuation for non–face-to-face services while developing evaluation and management codes to permit appropriate payment for disease management, education, and preventive services, all of which are crucial to chronic care management.

APPLICABILITY TO PEDIATRICS

Although coding and payment policies are primarily driven by the adult Medicare component of the CMS, recently both *CPT* and the RUC have been much more responsive to the needs of pediatric patients. However, if access to efficient and effective health care for all children is to be ensured, Medicaid and other payers must recognize and pay for all of the *CPT* codes, including those for immunization administration, non–face-to-face services, and children's screening services. The AAP believes that it is essential that the CMS publish values for all codes valued by the RUC, including those that may not be applicable to the adult Medicare population, but are still essential for comprehensive pediatric care.

National Correct Coding Initiative

Under provisions outlined in the ACA, Medicaid agencies must use Medicare's National Correct Coding Initiative (NCCI) edits to determine payment policy. The CMS developed the NCCI to promote national correct coding and to control improper coding, which had been resulting in inappropriate payments for Medicare Part B claims. NCCI policies are based on coding conventions defined in *CPT* guidelines, national and local policies and edits, coding guidelines developed by national societies, analysis of standard medical and surgical practices, and

review of current coding practices. The AAP is provided an opportunity to review and comment on these edits before their publication, giving the pediatric community 1 more opportunity to advocate that children's access to needed services not be compromised by exclusively adult-oriented payment decisions.

Pediatric National Payment Representation

The AAP has representation on the *CPT* Editorial Panel, the RUC, the *International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM)* Editorial Advisory Board, and the *International Classification of Diseases, Eleventh Revision (ICD-11)*, Pediatric Topic Advisory Group. This representation provides the AAP with a consistent voice, respected by adult specialty society colleagues and national payers. State- and payer-specific payment decisions that conflict with national rules or policies and that disadvantage children are being addressed through the active involvement of AAP members, state AAP chapters, and AAP chapter pediatric councils.

The ACA has also recognized the importance of services to children by mandating that, by 2014, all Medicaid programs use the Medicare CF as the floor for a large percentage of services provided in the office by primary care physicians. Although the AAP supports this attempt to equalize payments for services provided to adults and children, it continues to advocate for inclusion of all evaluation and management and procedural services provided to children and for a base Medicaid CF for pediatric services that exceeds Medicare's base to ensure that all children have access to care in a medical home. In addition, the AAP supports the development of a value-based reimbursement system that will additionally reward practices

and providers that demonstrate high quality and superior health outcomes in the patients they serve.

National Pediatric Database

The Medicare system uses a single national database (Medicare Part B Database) to track use of services to adults, allowing the CMS to identify policy and payment changes that negatively affect access to services or identify overuse of new or high-cost services. The absence of a single national database for Medicaid makes similar analyses for pediatric care challenging or impossible and limits important research tracking relationships between pediatric access to care, use of services, and quality outcomes. The AAP continues to actively lobby for a single national Medicaid database.

COMPONENTS OF THE RBRVS PAYMENT SYSTEM

The RBRVS system assigns a numeric value to each of 3 RBRVS components:

- Physician work
- Practice expense
- Professional liability insurance expense

Physician Work

The work a physician expends in directly providing a service or performing a procedure is called "intra-service work." In the office setting, the intra-service period is defined as face-to-face patient encounter time. In the hospital setting, it is the time spent on the patient's unit or floor, and for surgical procedures, it is the period from initial incision to the closure of the incision. Work performed before and after provision of a service is referred to as "pre-service work" and "post-service work," respectively. When pre-service, intra-service, and post-service works are combined, they create the

“total work” involved in the provision of that service.

Practice Expense

The practice expense component of the RBRVS includes the cost of clinical staff time, medical supplies, and medical equipment. In aggregate, practice expense accounts for an average of 44.8% of a code's total RVU. Increased paperwork, reporting regulations (eg, immunization registries and reportable quality indicators), and expenses involved in transitioning to electronic health records are common to all pediatric practitioners. The practice expense values for an office (non-facility) service will be higher than those for services provided in a hospital or other facility not owned by the provider, because much of the facility practice expense is covered under Medicare Part A, and physician services are covered under Medicare Part B; hence, some procedures have differing RVUs depending on whether they are performed in a “facility” as opposed to the practitioner's office.

Since 1998, the CMS has used a formula for calculating practice expense that allocates the costs of providing a specific service uniformly across all specialties by using expert panels to decide each of 6 categories of costs involved in each type of patient encounter: clinical labor, medical supplies, medical equipment, office expense, administrative labor, and all other expenses.

Professional Liability Insurance Expense

RBRVS assigns RVUs to cover the professional liability insurance expense incurred by physicians in providing each service. Similar to practice expense, these costs are normalized for all specialties providing that service.

Geographic Practice Cost Indices

The Omnibus Budget Reconciliation Act of 1989 also introduced the concept of

geographic practice cost indices to address the disparity in the cost of living in urban (37% higher) versus rural practices. Each component of the total RVU (physician work, practice expense, and professional liability insurance) is subjected to different correction values with states varying in the number of regions that are assigned different geographic practice cost indices.

RBRVS CONVERSION

Conversion from RVUs to payment amounts is a multistep process that is covered in detail in the RBRVS Brochure and RBRVS Conversion Spreadsheet from the AAP.

HIPAA CODE SETS AND DISEASE CLASSIFICATION

HIPAA established standard transaction codes for medical claims submission. The primary codes for reporting physician encounters include the Healthcare Common Procedure Coding System (HCPCS) Level I and Level II codes for procedural reporting and the *ICD-9-CM* codes for diagnosis reporting.

The *International Classification of Diseases* (ICD),² published by the World Health Organization, is used to code for a diagnosis, symptom, condition, or event linked to a provided service. The current clinical modification in the United States (ie, *ICD-9-CM*)¹ has been in use since 1979. Conversion to *ICD-10-CM*, in use internationally since 1994, is expected in the United States on October 1, 2015. The 7-digit alphanumeric system of *ICD-10-CM* allows for greater specificity for tracking illnesses, injuries, and disease-management programs. The AAP supports this transition to *ICD-10-CM* and is well positioned within the World Health Organization topical advisory groups to ensure that the Eleventh Revision of the ICD contains accurate, current, and comprehensive pediatric diagnoses and nomenclature.

HCPCS Level I Codes: CPT

HCPCS Level I codes are also called *CPT* codes. *CPT* is a listing of descriptive terms and identifying codes for reporting medical services and procedures developed and maintained by the American Medical Association. The *CPT* nomenclature comprises 3 categories of codes.

Category I CPT Codes

Category I *CPT* codes describe a procedure or service identified with a 5-digit *CPT* code and descriptor nomenclature. Category I *CPT* codes must represent services or procedures that are approved by the Food and Drug Administration, widely used in practice, and evidence based.

Category II CPT Codes

Category II *CPT* codes are supplemental tracking codes, without assigned RVUs, that are used to report adherence to quality indicators, adherence to clinical guidelines, and suggested best practices. Their use is encouraged, although not required. When reported, they facilitate quality data collection that support nationally established performance measures.

Category III CPT Codes

Category III *CPT* codes are temporary tracking codes, also without assigned RVUs, that allow for tracking new and emerging technologies while further studies determine whether they have sufficient use and more convincing literature support to qualify as Category I *CPT* codes.

HCPCS Level II Codes

HCPCS Level II codes, commonly referred to as HCPCS (“hick-picks”) codes, are used to identify services not included in the *CPT* nomenclature (eg, ambulance services, durable medical equipment, prosthetics, orthotics, and supplies)

that are developed and assigned by the CMS without direct input from the specialty societies. HCPCS Level II codes are alphanumeric codes, consisting of a single alphabetical letter followed by 4 numeric digits and are used to report office supplies such as injectable drugs and inhalation solutions as well as some orally administered drugs.

RECOMMENDATIONS

1. In the absence of more global reimbursement systems, the principles embodied by the fully implemented RBRVS system should continue to be the preferred process to establish physician payment, while recognizing a need to strive toward more parity between cognitive and procedural services, including complex chronic care, behavioral/mental health, and non-face-to-face services.
2. RBRVS values for CPT codes should accurately reflect the complexity of both cognitive and procedural physician work, comprehensive practice expense, and professional liability insurance expense in providing services

to infants, children, adolescents, and young adults.

3. The CMS should publish all RUC-recommended values, not just those that are applicable to the Medicare population.
4. The RUC process should accurately assess the nonprocedural physician work, practice expense, and professional liability insurance expense included in the provision of health care services to infants, children, adolescents, and young adults. To accomplish this, the RUC survey instrument, which is used to obtain estimates of the time and complexity required in performing a procedure to estimate a recommended professional work value, should be revised to allow for the accurate valuation of nonprocedural cognitive services.
5. Nationally, the education of pediatricians and pediatric subspecialists within AAP entities should be pursued to better understand the RUC survey instrument and the elements of physician work toward encouraging robust RUC survey participation among AAP members.

6. All payers, including Medicaid, should pay for the full spectrum of CPT codes and recognize CPT guidelines.

abstract

FREE

Atopic dermatitis is a common inflammatory skin condition characterized by relapsing eczematous lesions in a typical distribution. It can be frustrating for pediatric patients, parents, and health care providers alike. The pediatrician will treat the majority of children with atopic dermatitis as many patients will not have access to a pediatric medical subspecialist, such as a pediatric dermatologist or pediatric allergist. This report provides up-to-date information regarding the disease and its impact, pathogenesis, treatment options, and potential complications. The goal of this report is to assist pediatricians with accurate and useful information that will improve the care of patients with atopic dermatitis. *Pediatrics* 2014;134:e1735–e1744

Atopic dermatitis (AD), commonly referred to as eczema, is a chronic, relapsing, and often intensely pruritic inflammatory disorder of the skin. A recent epidemiologic study using national data suggested that the pediatric prevalence is at least 10% in most of the United States.¹ AD primarily affects children, and disease onset occurs before the ages of 1 and 5 years in 65% and 85% of affected children, respectively.¹

The number of office visits for children with AD is increasing.² Up to 80% of children with AD are diagnosed and managed by primary care providers, often pediatricians.³ Although medical subspecialists, such as pediatric dermatologists and/or pediatric allergists, may be suited to provide more advanced care for children with AD, lack of a sufficient number of such physicians, particularly pediatric dermatologists,⁴ likely means the burden of AD care will continue to fall to primary care providers. Although consensus guidelines and practice parameters regarding the management of AD in children have been published,^{5–10} considerable variability persists in clinical practice, particularly regarding the roles that bathing, moisturizing, topical medications, and allergies play in management. Inconsistencies in opinion and treatment approach as well as the chronic and relapsing nature of AD can lead to frustration for the patient, family, and primary care providers when managing AD.

STATEMENT OF THE PROBLEM

New data support the theory that AD results from primary abnormalities of the skin barrier,¹¹ suggesting that skin-directed management of AD is of paramount importance. This clinical report reviews AD and provides an up-to-date approach to skin-directed management that is based on pathogenesis. Effectively using this information to create treatment plans

and educate families should help pediatric primary care providers manage most children with AD, thereby improving patient satisfaction and clinical outcomes.

CLINICAL FEATURES

The diagnosis of AD is primarily clinical (Table 1). Major clinical features are a pruritic and relapsing eczematous dermatitis in a typical distribution that changes with age.⁹ In infancy, the cheeks, scalp, trunk, and extremities are most commonly affected. In early childhood, the flexural areas are characteristic, whereas in adolescents and adults, hands and feet are typically involved. Pruritus is a hallmark of AD, which is often referred to as the “itch that rashes.” Other features that support the diagnosis of AD include early age of onset, personal or family history of atopy, ichthyosis vulgaris, and/or xerosis. It is important to exclude other inflammatory skin conditions, such as contact dermatitis, seborrheic dermatitis, and psoriasis. Skin biopsies and laboratory testing are usually unnecessary and not helpful in making the diagnosis of AD, although they may be beneficial when trying to exclude

conditions that appear similar to AD (such as those mentioned previously), particularly in patients whose symptoms are not responding to standard skin-directed care.

EFFECTS ON QUALITY OF LIFE

The effects of AD on the quality of life (QoL) of patients and their families cannot be underestimated. Nearly 50% of children with AD report a *severely* negative effect of the disease on QoL.¹² Factors that contribute to poor QoL in AD are fatigue and sleep deprivation (which directly correlate with itch and severity of AD), activity restriction, and depression. Children with severe AD also tend to have fewer friends and participate in fewer group activities than their peers.¹³ These children may be at higher risk of depression, anxiety, and other mental health disorders.¹⁴

AD also has a negative effect on QoL of caregivers and parents of affected children.¹⁵ Parents of children with moderate and severe AD spend up to 3 hours per day caring for their children's skin. The most commonly reported negative effects on parents are lack of sleep (often because of cosleeping), fatigue, absence of privacy (because of cosleeping, disrupted sleep of affected children), treatment-related financial expenditures, and feelings of hopelessness, guilt, and depression. In fact, the depression rate in mothers of children with AD is twice as high as in mothers of children with asthma.¹⁶ Appropriate social and community support resources, such as referral to a counselor, psychologist, or patient support groups, such as the National Eczema Association (www.nationaleczema.org), can be helpful when QoL issues are encountered in patients and families with AD.

PATHOGENESIS

The pathogenesis of AD is complex and multifactorial. Skin barrier dysfunction,

environmental factors, genetic predisposition, and immune dysfunction all play a role in its development and are closely intertwined. In the past, emphasis had been placed on T helper cell dysregulation, production of immunoglobulin E (IgE), and mast cell hyperactivity leading to the development of pruritus, inflammation, and the characteristic dermatitis.¹¹ Recent discoveries, however, have established the key role of skin barrier dysfunction in the development of AD.¹⁷

The primary function of the skin barrier is to restrict water loss and to prevent entry of irritants, allergens, and skin pathogens. The outermost layer of skin, called the stratum corneum, is critical to the integrity of the skin barrier, with the protein filaggrin being a key player in stratum corneum structure and formation.¹⁸ Loss-of-function mutations (of which more than 40 have been described) in *FLG*, which encodes filaggrin, have been implicated in up to 50% of patients with moderate to severe AD in some demographic populations.^{17,19} Mutations in *FLG* are associated with a two- to threefold increased risk of having AD.²⁰

There are several proposed mechanisms of how filaggrin defects contribute to the development of AD. Inadequate filaggrin production leads to a reduced ability of keratinocytes to maintain hydration and to restrict transepidermal water loss, which then leads to xerosis, which in turn produces pruritus and, subsequently, AD.²¹ An inadequate skin barrier might also allow for the entry of aeroallergens, leading to an inflammatory response, causing AD. Another theory speculates that local pH may be changed with an altered skin barrier, leading to the overgrowth of bacteria, such as *Staphylococcus aureus*, which then may trigger an innate immune response, leading to the development of inflammatory skin lesions. Regardless of the mechanism,

TABLE 1 Clinical Features in AD^{5,6,9}

Major clinical features
Itching/pruritus
Typical dermatitis with a chronic or relapsing history
Patient or family members with atopy
Typical distribution and age-specific patterns
Minor clinical features
Early age of onset
Dry skin/xerosis
Keratosis pilaris
Ichthyosis vulgaris
Lip dermatitis
Hand eczema
Lichenification
Elevated IgE level
Itching on sweating
Recurrent infections
Pityriasis alba
Dermatographism
Eye symptoms: cataracts, keratoconus, inflammation

this new knowledge reinforces the primary role of the skin barrier in the pathogenesis of AD and highlights the need for skin-directed therapy to repair or enhance the function of the skin barrier.

ALLERGIES AND AD

The relationship between AD and food allergy is complex but likely over-emphasized. More than 90% of parents incorrectly believe that food allergy is the sole or main cause of their child's skin disease.²² The resulting focus on food allergy can result in elimination diets; potential nutritional concerns, such as protein or micronutrient malnutrition or deficiencies; and misdirection of treatment away from the skin, thereby leading to undertreatment. Effective treatment of the skin tends to allay parental concern regarding food allergy.²³

True food-induced AD is rare. The most common cutaneous manifestations of food allergy are often IgE-mediated and consist of acute urticaria, angioedema, contact reactions, or in some cases, an increase in AD symptoms.^{24,25} In the case that AD is worsened by exposure to a food allergen, these reactions are not IgE-mediated but rather delayed-type hypersensitivity reactions and usually develop 2 to 6 hours after the exposure to the food.²⁶

The accentuated role of food allergies in AD may stem from the observation that food allergies are prevalent in patients with AD. The prevalence of food allergy in all children in the first 5 years of life is approximately 5%.²⁴ In children with AD, however, the prevalence of food allergy is approximately 30% to 40%,²⁵ and up to 80% will have high food-specific IgE concentrations, even in the absence of a true food allergy.²⁷ In addition, patients who have food allergy often have earlier-onset and more severe AD, and patients with early-onset AD have a higher

risk of developing food allergies than those with later-onset AD.²⁸ However, it is important to stress that this relationship is not causative. Rather, the presence of food allergy predicts a poor prognosis of severe and persistent AD, but food allergy does not necessarily cause AD.

Recent guidelines set forth by the National Institute of Allergy and Infectious Diseases (NIAID) support this position. In these guidelines, the NIAID states: "In some sensitized patients...food allergens can induce urticarial lesions, itching and eczematous flares, all of which may aggravate AD" but do not cause AD. They also state that, in the absence of documented IgE- or non-IgE-mediated food allergy, there is "...little evidence to support the role for food avoidance" in the treatment of AD.²⁵ Egg allergy may be one exception, as up to half of infants with egg-specific IgE may have improvement in their AD when following an egg-free diet.²⁹ The NIAID guidelines state that allergy evaluation (specifically to milk, egg, peanut, wheat, and soy) should be considered in children younger than 5 years with severe AD if the child has persistent AD despite optimal management and topical therapy or if the child has a reliable history of an immediate cutaneous reaction after ingestion of a specific food.

The "atopic march" is the concept that AD is the first stop in the progression to other allergic disorders, such as asthma and allergic rhinitis.³⁰ It has been suggested that early optimal and successful treatment of AD may prevent or attenuate the development of other atopic conditions.³¹ The recent findings of the role *FLG* mutations play in causing epidermal barrier defects, thus allowing for the entry of aeroallergens and other allergens into the skin and subsequent epicutaneous sensitization, lends strong support to this possibility and highlights the importance of effective skin-directed treatment of AD.

Allergic contact dermatitis (ACD) is a delayed hypersensitivity reaction to cutaneous allergens that is underestimated in the pediatric population and likely plays a greater role in perpetuating AD than was previously believed. Up to 50% of children with difficult-to-control AD have at least 1 positive patch test reaction to a cutaneous allergen.³² Not all positive reactions may be relevant, however. Most studies estimate 50% to 70% of all positive reactions to be relevant in patients with suspected ACD. Thus, the possibility of ACD should be considered in children with unusual or difficult-to-control AD.

TREATMENT PRINCIPLES

Skin-directed therapies should be the first approach to management. This approach has 4 main components, each focusing on a specific manifestation of AD: (1) maintenance skin care, designed to repair and maintain a healthy skin barrier; (2) topical antiinflammatory medications, to suppress the inflammatory response; (3) itch control; and (4) managing infectious triggers, recognition and treatment of infection-related flares. Education of patients and families is another critical factor that should not be overlooked. AD is a frustrating disease because of its recurrent nature, even in the face of excellent care plans. When the primary care provider is able to set realistic expectations regarding outcomes, parental compliance is better and frustration is decreased. It can be helpful to discuss the prognosis of AD, because most children will outgrow the symptoms or at least the severity of the disease.²⁷ Patients whose parents receive comprehensive education regarding AD and its care have better improvement in AD severity than patients whose parents do not receive this education.³³ Written action plans have been shown to improve adherence in children with asthma, and a similar

model for patients with AD (see Fig 1 for an example), outlining specific indications for different products and medications, is likely to be helpful.^{34,35}

Maintenance Skin Care

Maintenance skin care is the foundation of AD management; its goal is to repair and maintain a functional skin barrier. Patients should be instructed to develop these habits and perform them daily. Preliminary evidence supports the role of maintenance skin care in helping to reduce both the frequency and severity of AD flares. The key facets of maintenance care include maintaining skin hydration and avoiding irritants and triggers.

The optimal frequency of bathing for children with AD has not been well

studied and remains controversial. Soaking baths allow the skin to imbibe moisture, and a daily bath can be beneficial in patients with AD as long as a moisturizer is applied afterward.^{30,36} The specific frequency of bathing should be titrated to the individual patient and his or her response to bathing. The use of lukewarm water and limiting the duration of the bath can prevent skin dehydration. Cleansing may also remove bacteria from the skin surface. A mild synthetic detergent without fragrance can be used to cleanse soiled areas without fear of exacerbating the skin disease. Additives are not proven to be effective, although dilute bleach can be helpful for patients who are prone to infection

and flares (see Managing Infectious Triggers).

A second and extremely important component of maintaining skin hydration is lubrication of the skin, commonly referred to as moisturization. Frequent moisturization alleviates the discomfort associated with xerosis, helps to repair the skin barrier, and reduces the quantity and potency of pharmacologic interventions.^{37,38} In a British study evaluating 51 children with AD, parents were educated on the proper use of moisturizers and topical treatments by a nurse specialist. During the study period, the quantity of moisturizer used increased 800% (average use of 426 g per week per patient) while the severity of AD decreased and the percentage of patients having to use moderate or potent topical steroids decreased.³⁹

Studies comparing the relative effectiveness of specific moisturizers are lacking, and the plethora of products can make the task of choosing a moisturizer daunting. Simplistically, all moisturizers are mixtures of lipid (liquid or semisolid) and water. Ointments have the highest proportion of lipid (for example, petroleum jelly is 100% lipid) and likewise feel “greasy” when applied to the skin. Creams are emulsions of water in lipid (oil>water) and contain preservatives and stabilizers to keep these ingredients from separating. Although creams can be less greasy than ointments, the added ingredients can sometimes burn or sting atopic skin. Similarly, lotions are also emulsions with a higher proportion of water to lipid than creams. Frequent reapplication of lotions is needed to maintain skin hydration. In general, ointments tend to have the greatest moisturizing effect, followed by creams, and then lotions. The best moisturizers for patients with AD are fragrance free and have the least possible number of preservatives, because these are potential irritants.

An Action Plan to Guide the Care of Your Child's Atopic Dermatitis (Eczema)

1. If your child enjoys a bath, allow him or her to soak daily in lukewarm water for 10 to 15 minutes. If your child does not enjoy a bath or if you feel water irritates his or her skin, bathe every 2 to 3 days. Use a gentle cleanser for dirty areas only at the end of the bath.
2. After the bath, pat the skin dry, leaving it damp to the touch.
3. Prescription medications should be applied to areas of the skin that are red, rough, and itchy. These medications should be applied in a thin layer.
 - Apply _____ to affected areas of the face, neck, armpits, and groin.
 - Apply _____ to affected areas of the body.
4. Apply a moisturizer (preferably a cream or ointment) over the entire face and body. Your child's skin medications and moisturizer should be put on within a few minutes after the bath so the skin does not dry out.
5. Repeat steps 3 and 4 a second time each day if instructed by your doctor.
6. Moisturizer can be applied as often as needed to dry, itchy skin. Prescription skin medications should not be used more than 2 times daily.
7. Continue the prescription skin medications until the red, rough rash is gone. If the flare of the rash has not improved in 2 weeks, talk with your doctor.
8. After the rash has cleared, continue to moisturize all areas of the face and body daily.
9. Restart the prescription skin medications as directed when the rash returns.
10. Antihistamines can help with itching and poor sleep due to eczema.
 - Give _____ 30 minutes before bedtime when your child is itchy.
 - Give _____ in the morning as needed for itching.
11. Oozing, drainage, pus bumps, and yellow crusts can indicate the skin is infected. Talk with your doctor right away if you are concerned about skin infection.

FIGURE 1

An action plan for the management of AD.

Moisturizers should be applied at least once daily to the entire body, regardless of whether dermatitis is present. There are a handful of prescription barrier creams marketed for the treatment of AD. These products do not have active pharmacologic ingredients. A small study compared 2 of these products with an over-the-counter ointment and revealed no significant difference in efficacy for patients with mild-to-moderate AD, as defined by investigator global assessment.⁴⁰ Although no major adverse effects have been reported with these products, they are considerably more expensive and may, therefore, be less cost effective than standard moisturizers.

Multiple patient-specific factors, commonly referred to as triggers, may exacerbate AD. Triggers may be unavoidable, but minimizing exposure to them can be helpful. Common triggers may include aeroallergens or environmental allergens, infections (particularly viral illnesses), harsh soaps and detergents, fragrances, rough or non-breathable clothing fabrics, sweat, excess saliva, and psychosocial stress.

Topical Antiinflammatory Medications

The eczematous dermatitis seen in AD is the manifestation of an inflammatory immune response in the skin. Flares of dermatitis are unlikely to respond to moisturization alone, and during these times, treatment is focused on suppressing the inflammatory response. Topical steroids are the first-line, most commonly used medications to treat active AD and have been used for the last 40 to 50 years.³⁰ When used appropriately, they are effective and safe.⁴¹ However, when used inappropriately, there are potential risks of cutaneous atrophy, striae, telangiectasia, and systemic absorption with resulting adrenal suppression. There are also other potential

local effects when used around the eyes (intraocular hypertension, cataracts) or mouth (periorificial dermatitis). Because of these potential risks, there is a real phenomenon of “steroid phobia” on the part of both parents and health care providers. Although this phobia does not correlate with AD severity, it does lead to undertreatment of the skin disease.^{42,43}

Topical steroids are classified according to their potency, ranging from class VII (low potency) to class I (super potent; Table 2). Class I medications are 1800 times more potent than the least potent class VII medications. Risk of adverse effects directly correlates with potency, with high-potency and super-potent topical steroids carrying the greatest risk. When treating most cases of AD, high-potency medications are generally not needed. Patients treated with higher-potency topical steroids are at risk for developing the aforementioned adverse effects, making close follow-up necessary. Choosing an appropriate topical steroid can be difficult, given the number of different medications, and health care providers are advised to rely on 2 or 3 medications from the low- (classes VI and VII) and moderate-potency groups (classes III, IV, and V) as “go-to” medications for everyday practice. These choices may be based on regional prescribing practices and insurance coverage or cost. Inexpensive low- and moderate-potency generic topical steroids are hydrocortisone and triamcinolone, respectively. Acceptable “limits” of topical steroid potency in a primary care practice are low-potency topical steroids for the face, neck, and skin folds and moderate-potency topical steroids for the trunk and extremities.

For acute flares and moderate to severe cases, wet wrap therapy (also called wet dressings) can be used in conjunction with topical steroids to

TABLE 2 Topical Steroid Medications by Class

Class I: Superpotent
Clobetasol propionate 0.05% ointment, cream, solution, and foam
Diflorasone diacetate 0.05% ointment
Fluocinonide 0.1% cream
Halobetasol propionate 0.05% ointment and cream
Class II: High potency
Betamethasone dipropionate 0.05% ointment and cream
Budesonide 0.025% cream
Desoximetasone 0.25% ointment and cream
Diflorasone diacetate 0.05% cream
Fluocinonide 0.05% ointment, cream, and gel
Halcinonide 0.1% cream and ointment
Mometasone furoate 0.1% ointment
Class III: Moderate potency
Betamethasone valerate 0.1% ointment, foam
Desoximetasone 0.05% cream
Diflorasone diacetate 0.05% cream
Fluticasone propionate 0.005% ointment
Triamcinolone acetonide 0.1% ointment
Triamcinolone acetonide 0.5% cream
Class IV: Moderate potency
Betamethasone valerate 0.12% foam
Clocortolone pivalate 0.1% cream
Flurandrenolide 0.05% ointment
Fluocinolone acetonide 0.025% ointment
Halcinonide 0.025% cream
Hydrocortisone valerate 0.2% ointment
Mometasone furoate 0.1% cream and lotion
Triamcinolone acetonide 0.1% cream
Class V: Moderate potency
Betamethasone valerate 0.1% cream
Clocortolone pivalate 0.1% cream
Flurandrenolide 0.025% ointment
Flurandrenolide 0.05% cream
Fluocinolone acetonide 0.01% cream
Fluocinolone acetonide 0.025% cream
Hydrocortisone butyrate 0.1% ointment, cream, and lotion
Hydrocortisone probutate 0.1% cream
Hydrocortisone valerate 0.2% cream
Prednicarbate 0.1% cream
Triamcinolone 0.025% ointment
Class VI: Low potency
Alclometasone dipropionate 0.05% ointment and cream
Desonide 0.05% ointment, cream, lotion, hydrogel, and foam
Fluocinolone acetonide 0.01% oil
Flurandrenolide 0.025% cream
Triamcinolone acetonide 0.025% cream
Class VII: Low potency
Hydrocortisone 0.5% and 1% ointment and cream (over the counter)
Hydrocortisone 2.5% ointment, cream, and lotion

quickly control the dermatitis.⁴⁴ Wet dressings increase penetration of topical steroids into the skin, decrease

itch, and serve as an effective deterrent to scratching. The technique is straightforward: after a soaking bath, topical steroid is applied to affected areas followed by application of moisturizer to the rest of the skin; moist gauze or cotton clothing that has been dampened with warm water is then applied; the wet layer is covered with dry cotton clothing. Blankets and a warm room keep the child comfortable. The dressings can be left in place for 3 to 8 hours before being changed. Wet dressings can be used continuously for 24 to 72 hours or overnight for up to 1 week at a time.

Another consideration when prescribing topical steroids is the vehicle or form of product by which the active ingredient is delivered. Ointments are less likely to produce a burning or stinging sensation and are better tolerated by infants and younger children. When comparing the same active ingredient and concentration, ointments are more effective than creams or lotions, because their occlusive effect results in a higher relative potency. Topical steroids should be applied as a thin layer once or twice daily to affected areas until these areas are smooth to touch and no longer red or itchy. Traditionally, topical steroids are held when dermatitis is quiescent and restarted when the eruption recurs. Placing an absolute limit on the duration of topical steroid use can be confusing for families, leads to unsatisfactory outcomes, and conflicts with the relapsing nature of the disease itself. However, if AD is not responding after 1 to 2 weeks of treatment, reevaluation to consider other diagnoses or treatment plans is indicated. When these general guidelines are followed, the risk of adverse effects from the use of topical steroids is extremely low.

Topical calcineurin inhibitors (TCIs) are a newer treatment of AD. These medications are topical immunosuppressive

agents that inhibit T-cell function. There are currently 2 forms: tacrolimus ointment (available in 0.03% and 0.1%) and pimecrolimus 1% cream. Both are approved as second-line therapy for moderate-to-severe AD. A recent meta-analysis in pediatric patients with AD demonstrated that both tacrolimus and pimecrolimus are effective; tacrolimus is more effective than pimecrolimus, but both reduce the inflammation and pruritus associated with AD.⁴⁵

TCIs have a different adverse effect profile than topical steroids and do not cause atrophy, striae, telangiectasia, and adrenal suppression. Thus, they are highly beneficial to treat AD in patients for whom concerns for adverse effects from long-term use of topical steroids are highest (eg, face, eyelids). The negatives, however, are a higher relative cost and the potential adverse effects of burning and stinging (tacrolimus > pimecrolimus). In addition, the Food and Drug Administration has issued a so-called “black box” or boxed warning for TCIs, citing a potential cancer risk with the medication, on the basis of the observation that laboratory animals exposed to high doses of systemic calcineurin inhibitors developed malignancies more frequently and on rare case reports of adult patients using TCIs who developed lymphoma and skin cancers.⁴⁶ However, the cause-and-effect relationship between TCI use and malignancy in these case reports is unclear. Reassuringly, TCIs have been used in children for more than 15 years, there have been no reports of malignancy in children, and there is little to no concern for systemic absorption or systemic immunosuppression.⁴⁷ Indeed, in 1 adult study, there was a lower rate of nonmelanoma skin cancer in patients with AD who used TCIs to treat their inflammatory disease.⁴⁸

Proactive Treatment

Although traditional AD management consists of treating active disease and flares with topical steroids and/or TCIs,

emerging data suggest that use of these medications when a patient is not having active disease may be helpful as well. In 1 study, patients used twice-daily antiinflammatory medications to treat active AD and were then randomly assigned to receive “proactive” twice-weekly treatment with topical tacrolimus or placebo. Patients who received topical tacrolimus had significantly less AD flares and increased time to new flare development when compared with those who received placebo.⁴⁹ A similar effect may also be true with topical steroids (fluticasone propionate and methylprednisolone aceponate have been studied),⁵⁰ although none of these studies have evaluated the long-term safety of this treatment regimen. The choice of medication used for flare prevention may depend on patient age, location of involvement, and cost.

Itch Control

Pruritus is another important component of AD. AD is commonly referred to as the itch that rashes; the associated pruritus may be significant, even in the absence of significant rash. Often, parents may be unaware of how much their child scratches, because itching is generally worse at night. The pathophysiology behind pruritus is complex, and both peripheral and central factors are involved.⁵¹ Examples of peripheral factors are irritant entry through a defective epidermal barrier, transepidermal water loss, and protease activity in the skin.⁵² Centrally, there is a complex interplay of multiple different mediators, although histamine seems to have a limited role, if any.^{52,53} Clinical factors can also promote itch, including scratching (the “itch-scratch” cycle), xerosis, psychological stress, sweat, and contact with irritants such as wool and aeroallergens.

It is often challenging to remove itch, even when a patient's skin is improving. Management of itch initially focuses on

minimizing triggers and continuing the skin-directed treatments of restoring the skin barrier and suppressing inflammation. Adjunctive systemic therapy can be added to help manage itch. Oral antihistamines do not have a direct effect on the dermatitis, but can help reduce the sensation of itching and, thus, decrease scratching and trauma to the skin in patients with AD flares.⁵⁴ Sedating antihistamines (such as diphenhydramine or hydroxyzine) should be used with caution in infants, who may be more prone to adverse effects of these agents. In addition, paradoxical effects of agitation instead of sedation may occur in some children. Nonsedating antihistamines (such as cetirizine and loratadine) are less effective on pruritus but can be helpful for patients who have environmental allergic triggers.⁵⁴ Topical antihistamines are not effective in the treatment of AD-associated pruritus and contain potential irritants and allergens that may worsen dermatitis.

Managing Infectious Triggers

Both bacterial and viral skin infections are associated with flares in children with AD. Affected patients, particularly those with poorly controlled AD, have a higher risk of cutaneous infections. The skin of patients with AD has an abnormal expression of antimicrobial peptides responsible for responding to bacteria or skin barrier compromise, toll-like receptor defects, and immune dysregulation in the form of diminished immune cell recruitment.⁵⁵ This combination of factors puts patients with AD at higher risk of skin infection.

Ninety percent of patients with AD are colonized with *S aureus*.⁵⁶ Pruritus may occur even in patients who are colonized but not actively infected. Many patients with AD have sudden exacerbations of their disease that can be attributed to active infection with bacteria, most commonly *S aureus*,

and active treatment of the infection subsequently improves the skin.⁵⁶ Clinical signs of infection, such as pustules, oozing and honey-colored crusts, and less commonly fever and cellulitis, may lead the primary care provider to prescribe antibacterial treatment. Secondary infection of AD is a clinical diagnosis and is often associated with flare of the underlying AD. Obtaining skin cultures, particularly of pustules and draining lesions, before treatment can be helpful in determining the causative pathogen but is not always necessary. The rate of methicillin-resistant *S aureus* (MRSA) colonization in patients with AD varies depending on the community in which the patient resides.⁵⁷ Streptococcal infections may also occur in patients with AD. Signs of streptococcal infection include pustules, painful erosions, and fever. In addition, patients may have facial or periorbital involvement and invasive infections.⁵⁸

There are multiple synergistic components involved in treating active *S aureus* and streptococcal infection in AD. Topical, oral, or intravenous antibiotic therapy may be needed depending on the extent and severity of infection. The specific medication used should be directed at *S aureus* and *Streptococcus*. Topical mupirocin can be used for limited skin lesions. Cephalixin is a common first-choice when oral antibiotics are needed and MRSA is not suspected. Repair of the skin barrier is continued simultaneously: bathing, moisturization, and topical anti-inflammatory therapies are all usually indicated. MRSA or other etiologies may be considered in patients who remain refractory to treatment.

Dilute bleach baths may have a useful role in the management of patients with AD, particularly those prone to recurrent infection and AD flares. A recent placebo-controlled, blinded study examined the effects of 0.005% bleach

baths plus intranasal mupirocin versus placebo in children with moderate to severe AD. Patients bathed for 5 to 10 minutes twice weekly with the intervention. Those in the treatment group had significant improvement in their AD severity scores versus those in the placebo group.⁵⁶ Areas of the body that were not submerged in the bleach-containing water, specifically the head and the neck, revealed no difference in AD severity scores between the 2 groups. The treatment was well tolerated, without any adverse effect, and without any increase in resistant strains of *S aureus*. Although a relatively small study, the results provide support for the practice of using dilute bleach baths as one modality in the treatment of patients with AD. A concentration of 0.005% bleach is made by adding 120 mL (1/2 cup) of 6% household bleach to a full bathtub (estimated to be 40 gallons) of water. The amount of bleach should be adjusted based on the size of the bathtub and the amount of water in the tub.

Patients with AD are also at greater risk of viral skin infections. These include molluscum contagiosum, eczema herpeticum, the recently described atypical enteroviral infection attributable to Coxsackie virus A6 (the so-called “eczema coxsackieum”),⁵⁹ and vaccinia virus (the virus used in smallpox vaccine). Patients with eczema herpeticum present with shallow, “punched-out” erosions in areas of skin affected with or prone to AD. Similarly, the lesions seen with hand, foot, and mouth disease caused by Coxsackie virus A6 tend to localize to AD skin. In cases in which the diagnosis is not clear, viral studies are indicated.

Eczema herpeticum can be potentially life threatening and requires systemic treatment with acyclovir. In addition, adequate analgesia, skin care, and topical antiinflammatory medications are used. Secondary bacterial infection

often coexists with eczema herpeticum and should be treated appropriately as well. Herpetic keratitis is associated with periocular eczema herpeticum.⁶⁰ Smallpox vaccine uses a live vaccinia virus, and its use was resumed by the military in 2002. Although it is contraindicated for those with AD and in those who have a close contact with AD, rare cases of eczema vaccinatum have been reported. Eczema vaccinatum manifests as a rapidly developing papular, pustular, or vesicular eruption with a predilection for areas of AD, following inadvertent transmission of vaccinia virus from the unhealed inoculation site of the immunized person to a close contact with AD. Systemic dissemination may follow, and case fatality rates range from 5% to 40%. If eczema vaccinatum is suspected, infectious disease experts should be consulted, because treatment with cidofovir may be necessary.⁶¹

Final Points

Using this information, the pediatric primary care provider should be well equipped to treat most children with AD. If patients with suspected AD do not respond to these treatments, referral

to a pediatric medical subspecialist, such as a pediatric dermatologist, may be useful. Other reasons for referral include poorly controlled or generalized AD with consideration for systemic immunosuppressive therapy, recurrent infections (viral or bacterial) in the setting of AD, suspected ACD, and the presence of atypical features or physical examination findings. In cases of persistent, refractory, and/or generalized AD, systemic treatment, such as phototherapy or immunosuppressive medications, may be indicated. Oral steroids are generally not indicated because of their adverse side effect profile and a high likelihood of rebound dermatitis, making ongoing management difficult.

SUMMARY

AD can be a challenging and frustrating chronic disease for pediatric patients, parents, and primary care providers. Although the pathogenesis of AD is complex, recent research advances support the role of an abnormal skin barrier. The clinical corollary to these discoveries is a greater focus on skin-directed therapies as the first-line treatment of children with AD. This

includes maintenance skin care and the use of topical steroids for active disease. Low- and moderate-potency topical steroids are safe and effective for children when used appropriately. Early recognition and treatment of infectious complications can lead to improved patient outcomes. Patient and family education and counseling by the health care provider regarding the pathogenesis, specific treatment, and prognosis of the disease play an extremely important role in the management of AD.

FREE

Attention-deficit/hyperactivity disorder (ADHD) and substance use disorders are inextricably intertwined. Children with ADHD are more likely than peers to develop substance use disorders. Treatment with stimulants may reduce the risk of substance use disorders, but stimulants are a class of medication with significant abuse and diversion potential. The objectives of this clinical report were to present practical strategies for reducing the risk of substance use disorders in patients with ADHD and suggestions for safe stimulant prescribing. *Pediatrics* 2014;134:e293–e301

INTRODUCTION

Attention-deficit/hyperactivity disorder (ADHD) is the most common neurobehavioral disorder of childhood and occurs in approximately 8% of children and youth.^{1,2} It is characterized by deficits in attention in addition to hyperactivity and impulsivity that cause functional impairment in at least 2 settings.³ ADHD is considered a chronic condition.⁴ Stimulant medication is recommended as first-line therapy for school-aged children with ADHD, with implementation of behavioral therapy also recommended. Children with ADHD are at high risk of having co-occurring mental health and behavioral problems, including substance use disorders (SUDs).^{5,6} It is not clear whether stimulant treatment reduces the risk of SUDs in adolescents with ADHD. Some epidemiologic studies have found an inverse association between stimulant treatment and SUDs,^{7,8} although this association was not found in a study that examined the relationship between ADHD, stimulant medication, and conduct disorder.^{9,10} Stimulant medication can also have significant potential for misuse,¹¹ abuse, and diversion^{12,13} (ie, giving away, trading, or selling of prescription medication), which complicates care. Although the potential for misuse and diversion of stimulants has been studied,^{11,12} there is a paucity of recent research on the abuse potential of stimulants among children and adolescents. The objectives of the present clinical report were to review the literature and provide practical suggestions for optimizing ADHD care while minimizing misuse, abuse, and diversion of stimulant medication.

EPIDEMIOLOGY OF SUDS AMONG INDIVIDUALS WITH ADHD

Children and adolescents with ADHD are more likely to misuse alcohol, tobacco, and other illicit substances compared with children without ADHD.^{14,15} In a 2011 meta-analytic review of the prospective association of childhood ADHD and substance use, Lee et al¹⁴ included 27 longitudinal studies that followed up children with and without ADHD into adolescence or adulthood. The following demographic/methodologic factors did not significantly moderate the associations between childhood ADHD and substance outcomes: gender, age, race, publication year, sample source, version of the *Diagnostic and Statistical Manual of Mental Disorders* used to diagnose ADHD, family history of SUD, cognitive impairment, executive dysfunction, and family environment.¹⁶ Lee et al reported that, compared with control subjects without ADHD, children with ADHD were:

- twice as likely to have a lifetime history of nicotine use (odds ratio [OR]: 2.08, $P < .001$);
- nearly 3 times more likely to report nicotine dependence in adolescence/adulthood (OR: 2.82, $P < .001$);
- almost 2 times more likely to meet diagnostic criteria for alcohol abuse or dependence (OR: 1.74, $P < .001$);
- approximately 1.5 times more likely to meet criteria for marijuana use disorder (OR: 1.58, $P = .003$);
- twice as likely to develop cocaine abuse or dependence (OR: 2.05, $P < .001$); and
- more than 2.5 times more likely to develop an SUD overall.

ADHD is associated with an earlier age at onset of substance use and a higher likelihood of use of a variety of substances.^{17–19} Brook et al²⁰ reported that the diagnosis of ADHD poses an increased risk of SUD into adulthood;

meeting criteria for a diagnosis of ADHD in adolescence is associated with developing SUDs in a subject's 20s and 30s. Among individuals with ADHD, the number of inattention and hyperactivity/impulsivity symptoms exhibited is positively correlated with risk of substance use.²¹ Debate exists regarding whether the inattentive versus hyperactive/impulsive subtypes of ADHD confer different risk.^{22–26}

EXPLORING THE BIOLOGICAL AND ENVIRONMENTAL BASIS OF THE RELATIONSHIP BETWEEN ADHD AND SUD

To date, the mechanisms underlying the association between ADHD and SUDs are not completely understood, although several theories have been proposed. Impulsivity is associated with an increased risk of substance use,²⁷ a prerequisite for developing an SUD. It is also possible that impulsivity and poor judgment associated with ADHD contribute to the development of SUDs.²⁸ However, executive functioning deficits and increased substance use seem to be only one piece of the puzzle.²⁹ In addition to difficulty with executive functioning and poor judgment, which may lead to trying substances, individuals with ADHD may also be biologically more vulnerable to developing addiction than their peers without ADHD.

Dopamine transmission is central to current models of both ADHD and SUDs.^{30–32} Compared with unaffected control subjects, individuals with ADHD have greater dopamine transporter density, which may result in rapid clearance and low levels of synaptic dopamine.³³ Drugs of abuse, including cocaine, amphetamine, methamphetamine, Ecstasy, nicotine, alcohol, opiates, and marijuana, all increase synaptic dopamine concentrations, most notably in the brain's reward center, the nucleus accumbens.³⁴

Stimulant medications manage ADHD symptoms by increasing synaptic dopamine concentrations in the striatum (which includes the nucleus accumbens) via presynaptic transporters.³⁵ Theoretically, some individuals with ADHD may use substances to increase synaptic dopamine concentrations as a form of self-medication.³⁶ Another theory proposes a common genetic factor underlying both ADHD and risk of SUDs, although more studies are needed to further evaluate this association.^{37,38}

Children and adolescents with ADHD have higher rates of grade retention and school dropout than those without ADHD.^{39,40} These academic failures may increase an individual's likelihood to use drugs as a means to escape anxiety about school.⁴¹ Academic failures may also cause changes in peer groups, placing the individual with ADHD in social settings with others who have experienced school problems and are at a higher risk of alcohol and drug use.^{42,43}

TREATING ADHD AND CO-OCCURRING MENTAL HEALTH DISORDERS TO REDUCE THE RISK OF SUDS

Treatment of ADHD May Reduce the Risk of SUDs

Treatment of ADHD symptoms with stimulant medication may reduce the risk of developing SUDs.^{7,44} Biederman et al⁴⁵ determined that pharmacotherapy was associated with an 85% reduction in risk of SUDs in youth with ADHD. Timing of treatment matters: children with ADHD who are treated with stimulant medication at a younger age are less likely to use substances than those who have delayed onset of treatment.⁴⁶ Behavioral therapy may also confer some protection against substance use. Findings from the Multimodal Treatment Study of Children with ADHD revealed that

behavioral interventions afforded protection from SUDs at 24 months' post-intervention but not at 36 months.⁴⁷ The optimal age at which to begin treatment of ADHD to decrease the risk of substance use has not been established. The American Academy of Pediatrics (AAP), in its clinical practice guidelines for ADHD,⁴ recommends treating ADHD symptoms in children 6 years and older by using both behavioral interventions and medications approved by the US Food and Drug Administration. The AAP recommends that ADHD symptoms in children as young as 4 years be treated with behavioral interventions and possibly medications. In this context, treatment of ADHD symptoms is recommended as soon as the diagnosis of ADHD is made. Symptoms of ADHD often persist into adulthood,^{48,49} although optimal duration of medication treatment has not been established. Maintaining children on medication while symptoms persist and monitoring for adverse effects seems to be a reasonable approach.

As noted in the AAP clinical practice guidelines for ADHD,⁴ at any point at which a clinician believes that he or she is not adequately trained or is uncertain about making a diagnosis or continuing with treatment, a referral to a pediatric or mental health subspecialist should be made. If a diagnosis of ADHD or other condition is made by a subspecialist, the primary care clinician should develop a management strategy with the subspecialist which ensures that the child will continue to receive appropriate care consistent with a medical home model wherein the primary care clinician partners with parents so that both health and mental health needs are integrated.

Treating Co-occurring Mental Health Disorders

Co-occurring mental health conditions are common in individuals with ADHD and are associated with increased SUD

risk. Brook et al²⁰ determined that conduct disorder mediated the association of ADHD and SUDs. Other studies have revealed that, even after controlling for conduct disorder, ADHD symptoms are associated with increased risk of both substance use and development of SUDs.^{18,25} Comorbid conditions, including depression, anxiety, and low self-esteem, have each been noted to confer increased risk of substance use in individuals with ADHD.^{5,17,25,50,51} These findings suggest that diagnosing and treating co-occurring conditions in individuals with ADHD may help to reduce the risk of developing SUDs.

STIMULANT MEDICATIONS

Stimulant medications are highly effective for children and adolescents in reducing the core symptoms of ADHD.⁵² The most commonly used preparations of stimulant medication are methylphenidate and amphetamine. Atomoxetine, a selective norepinephrine reuptake inhibitor, and long-acting guanfacine and clonidine, which are selective α_2 -adrenergic agonists, are also recommended for the management of some ADHD symptoms.⁴ However, the effect sizes (meaning likelihood of reducing ADHD symptoms compared with placebo) are lower for atomoxetine and long-acting guanfacine and clonidine than they are for the stimulant medications.

Stimulant medications are both more effective at treating ADHD symptoms⁵³ and much more commonly misused than nonstimulant medications. Pediatricians are thus in a position to prescribe a medication that can reduce both ADHD symptoms and the risk of developing an SUD and simultaneously pose a risk for abuse and diversion. An understanding of the factors associated with misuse, abuse, and diversion of stimulant medication may help to guide safe use. Table 1 lists the most commonly

used medications for ADHD and their suspected relative abuse potential.

The terms "misuse," "diversion," and "abuse" are all associated with improper use of medication, but they are different phenomena with different definitions. The term misuse includes the use of medications not prescribed to the individual and using medications in ways other than prescribed. Examples of misuse include taking larger or more frequent doses than prescribed or using someone else's medication to enhance performance.¹³ The most common reasons reported for stimulant misuse are to concentrate, study, and improve grades; "to party" and "get high"; and to experiment.^{54–57} Most individuals who misuse stimulant medications do so via oral administration, with intranasal insufflation ("snorting") less common.^{43,46} Adolescents who report snorting medications or using stimulants to "get high" may be at highest risk of stimulant abuse and dependence.⁵⁸ The term diversion means the transfer of medication from the person to whom it is prescribed to a person for whom it is not prescribed.¹³ The term substance abuse was used in the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition*, to refer to use associated with problems or risk that interfere with functioning. The term addiction refers to loss of control or compulsive use of a substance. In the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5), diagnostic terms were changed to SUD, mild/moderate/severe, depending on the number of positive criteria.³ Even though they are not formal diagnoses, the terms substance abuse and addiction will likely remain in the lexicon and retain their meaning for some time, particularly in reference to prescription medications.

TABLE 1 List of Most Commonly Used Medications for ADHD With Suspected Relative Abuse Potential

Stimulant Status	Medication Type	US Trade Name ^a	Suspected Relative Abuse Potential ^b	
Stimulants				
Short-acting/immediate release	Methylphenidate	Ritalin ^a	High	
		Methylin ^a	High	
		Dexmethylphenidate	High	
		Amphetamine-dextroamphetamine	High	
		Dextroamphetamine	Dexedrine	High
			DextroStat ^a	High
	LA/ER	Methylphenidate	ProCentra	High
			Metadate CD	Medium
			Metadate ER ^a	Medium
			Ritalin LA ^a	Medium
			Ritalin SR ^a	Medium
			Methylin ER	Medium
			Daytrana patch	Low
			Concerta ^a	Low
Dexmethylphenidate	Quillivant XR	Low		
	Focalin XR	Low		
	Dextroamphetamine	Dexedrine Spansule ^a	Medium	
	Amphetamine-dextroamphetamine	Adderall XR ^a	Medium	
	Lisdexamfetamine	Vyvanse	Low	
Nonstimulants				
α_2 -adrenergic agonists	Guanfacine	Intuniv	Low	
	Clonidine	Kapvay	Low	
Selective norepinephrine reuptake inhibitor	Atomoxetine	Strattera	Low	

CR, controlled release; ER, extended release; LA, long acting; XR, extended release; SR, sustained release.

^a Indicates that generic formulation is available.

^b Relative abuse potential is suspected based on length of action and formulation of medication.

Misuse of Stimulant Medications

Misuse and diversion of stimulant medications are more widespread problems than abuse or addiction.⁵⁹ Wilens et al⁵⁴ conducted a systematic review of the literature examining misuse and diversion of prescription ADHD medications. Of the 21 studies reviewed, rates of past-year non-prescribed stimulant use ranged from 5% to 9% in grade school and high school children and from 5% to 35% in college-aged individuals. In a large public university in the mid-Atlantic region, Arria et al⁵⁵ found that 18% of students who were not prescribed stimulants engaged in nonmedical stimulant use, more than one-quarter (26.7%) of students with diagnosed ADHD reported having used more medications than prescribed, and 15.6% reported using someone else's

prescription stimulants in their lifetime. Nonmedical use of prescription stimulants was associated with previous use of illicit substances as well as alcohol and marijuana dependence.

Diversion of Stimulant Medications

Diversion of stimulant medication is common. Between 16% and 23% of school-aged children reported that they have been approached to sell, give, or trade their prescription stimulant medication.^{60,61} Boys are more likely to divert their stimulant medications than girls.⁶² The most common source of diverted medications is friends and family members.⁶³ More than one-quarter of university students reported that diverted stimulant medications are easy or somewhat easy to obtain.⁵⁶ Individuals with ADHD who have co-occurring SUDs and/or conduct

disorders are more likely to both misuse and divert their stimulant medication,⁶⁴ as are white individuals, members of fraternities and sororities, and students with lower grade-point averages.^{54,65}

Abuse of Stimulant Medications

Methylphenidate and amphetamine both have known abuse potential, although there is little evidence that these drugs are widely abused by the patients to whom they are prescribed,⁵⁹ and evidence for abuse potential among children and adolescents is limited. "Subjective effect" (ie, how much a person likes a drug, achieves euphoria, experiences reinforcement with use) is an important factor considered in determining abuse potential of a substance. Among individuals without ADHD, both methylphenidate and amphetamine produce significant subjective effects; amphetamine is nearly twice as potent as methylphenidate at equivalent doses.⁶⁶ Research performed in the 1970s revealed that stimulants do not reliably produce these subjective effects in individuals with ADHD.⁶⁷ Fredericks and Kollins⁶⁸ found that individuals with ADHD displayed a higher preference for methylphenidate compared with placebo, although other measures of abuse potential, specifically participant-rated effects of methylphenidate on mood, were not elevated. Thus, the preference for methylphenidate may reflect its therapeutic efficacy rather than abuse potential. Most of the studies evaluating abuse potential of stimulant medications used short-acting preparations, and there is evidence that sustained-release and longer acting preparations have decreased abuse potential.^{59,69} Indeed, short-acting medications are more likely to be misused or abused, and amphetamine preparations are misused and abused more frequently than methylphenidate preparations.^{53,70,71}

SAFE STIMULANT-PRESCRIBING PRACTICES

In light of the high risk of SUDs among individuals with ADHD, pediatricians should seek to accurately diagnose ADHD and treat symptoms appropriately. Several precautions may help to reduce stimulant misuse, abuse, and diversion.

Before Prescribing, Confirm a Diagnosis of ADHD

Inattention is multifactorial. Many children or adolescents who are depressed, anxious, neglected, or having academic difficulty because of a learning disorder may present as inattentive. ADHD is a primary disorder of attention. According to the diagnostic criteria for ADHD in the DSM-5,³ ADHD symptoms must be present during childhood; thus, particular caution is warranted before making a new diagnosis of ADHD, especially in an adolescent. Although it is possible that symptoms in childhood were unnoticed, adolescents sometimes attempt to get a stimulant prescription by feigning symptoms of ADHD.⁷² The diagnosis of ADHD is made clinically in an individual who fulfills the criteria for ADHD listed in the DSM-5.³ Standardized tools, such as parent- and teacher-completed ADHD rating scales, assist in making a diagnosis and should be used in the assessment.⁷³ A thorough history, review of medical and school records, and a collateral parent interview may all help confirm a correct diagnosis. The criteria used for diagnosing ADHD and any history or evaluations that were made to rule out other conditions that might be confused with ADHD (eg, sleep disturbances, other learning disabilities, thyroid dysfunction) should be recorded in the patient's medical record. The AAP's Clinical Practice Guideline for ADHD provides specific guidance about diagnosis and management.⁴

Screen Older Children and Adolescents for Use of Alcohol, Marijuana, and Other Drugs

The AAP recommends screening, brief intervention, and referral to treatment as part of routine health care for older children and adolescents.⁷⁴ This recommendation is particularly important for adolescents with ADHD, who are more likely to use substances and to develop an SUD than their peers. Adolescents with ADHD who use alcohol, marijuana, or other substances are also more likely to divert stimulant medication and thus require increased attention and monitoring by their prescriber.

The AAP policy statement titled "Substance Use: Screening, Brief Intervention, and Referral to Treatment for Pediatricians"⁷⁴ provides a complete review of recommended screening tools and brief interventions for adolescent substance use. The AAP currently recommends the 3 "opening questions" associated with the CRAFFT tool (see the following text) to detect past-year substance use. Although currently an active area of National Institutes of Health-funded research,^{75,76} these questions have not been validated to date, and it is not known whether the "other drugs" question is sensitive enough for identifying misuse or abuse of prescription medications. An additional question (eg, "Have you ever used someone else's prescribed medication?") may be warranted to identify misuse, particularly before prescribing a stimulant medication for the first time.

"Opening questions" to identify past-year substance use:

In the past year, have you:

1. Had a drink with alcohol in it?
2. Used marijuana?
3. Used any other substance to get high?

Provide Anticipatory Guidance

Anticipatory guidance regarding proper use of stimulant medications should be part of every patient encounter in which medications for ADHD are discussed. Table 2 lists points that should be included in this discussion. The pediatrician should discuss that medications should only be taken as prescribed by the physician, even with very young children, in a developmentally appropriate manner. As children enter the upper elementary school years, the conversation should evolve to include discussion about the proper use of medication. Children and parents should be aware of the risk for misuse, diversion, and abuse. Children should understand that trading or selling stimulant medication is illegal. Children who live in areas of high-crime rates should have a concrete, realistic safety plan for managing their medication. For children who are 12 years and older, the discussion should also include information about careful transitioning of administration of medication. Although the child should not be pushed to start self-administering medication, having this discussion earlier with the family can alert them that transition of medication management from caregiver to child should be a gradual and carefully monitored one so that when the child is developmentally ready to assume more responsibility of medication management, there is a plan in place to ensure that the transition is safe.

Document Prescription Records

Stimulant medication is a Drug Enforcement Administration Class II controlled substance. Every prescriber must document and monitor the prescribing of stimulant medications. Requests for early refills should be explored and carefully documented to

TABLE 2 Discussion Points for Anticipatory Guidance Regarding Stimulants and Substance Use**Proper administration**

At each clinic visit, review with the patient how he or she is taking his or her stimulant medication.

- Only take the amount of medicine prescribed. Do not take extra medication.
- Take your stimulant medication exactly as prescribed. Do not change the dose or timing. Speak to your doctor if you do not think your medication is working as it should or if you are experiencing adverse effects.
- Do not use alcohol, tobacco, marijuana, or other illicit substances. Drug use worsens problems with attention, leads to medication noncompliance, and can interact with stimulant medication.
- If stimulant medication is administered at school, it should be dispensed at school nurse's office or other safe location with adult supervision.

Risk of misuse, diversion, and abuse

For people who do have ADHD, when stimulant medications are taken as prescribed, there is no increased risk of abuse; rather, stimulant medication appears to decrease the risk of developing an SUD.

- Explain that some people who do not have ADHD may take stimulant medications inappropriately.
- Inform patient and parent that children and adolescents may be asked to give away or sell their stimulant medications but should never do so. Parents may role play appropriate responses so that the child will be prepared if asked. Have the patient and parents keep medication in a safe location (either at home or in a locked office at school). Medications should never be carried in a backpack or purse.

Transition of care

Transitioning of administration of stimulant medication from caregiver to child/adolescent should be done incrementally. Parents and patients should be counseled that ADHD generally persists into adulthood.

- To start a transition, the child/adolescent must be able to remember to take medication as prescribed. Signs suggesting readiness should include the ability to name the medication, dose, and timing of administration as well as emerging signs of independence in other areas, such as being home alone, carrying a key, completing homework independently, or participating in care for a pet.
- The caregiver should continue to periodically supervise medication administration and monitor the child's/adolescent's overall school, social, and family functioning. Weekly pill dispensers can allow burgeoning autonomy for the child/adolescent while allowing the caregiver to monitor doses and control the supply.
- If concerns develop regarding medication misuse or diversion or use of other drugs, the parent should resume control of the medication, dispense each dose, and monitor carefully.

detect a pattern of frequent early requests. Similarly, it is important to document communications between multiple providers who share responsibilities for prescribing medications or altering treatment regimens for the same patient.

Prescribing Medications for ADHD in Context of Active SUD

Illicit substance use often results in attention difficulties, hyperactivity, and/or impulsivity, making a new diagnosis of ADHD difficult or impossible to distinguish from symptoms related to ongoing substance use. In these cases, reevaluation after a period of abstinence may be warranted.

Adolescents who have both previously diagnosed ADHD and an active SUD may be difficult to monitor because

symptoms of substance use may be indistinguishable from ADHD symptoms. In general, an active SUD should be treated (usually via referral to a mental health counselor or addiction specialist) before beginning medication to treat ADHD. However, for patients with well-documented ADHD that predates the onset of substance use, it may be reasonable to treat both disorders concurrently. Consultation with a psychiatrist or addiction specialist when managing complex patients is suggested.

When considering which ADHD medication to prescribe to a patient with a co-occurring SUD, a careful risk/benefit assessment must be conducted. If the patient is currently abusing prescription stimulants or there is a clear indication that the patient would sell or divert stimulant

medication, it may be best to start with a long-acting stimulant medication with low risk of misuse or diversion. Long-acting preparations, especially those with an osmotic controlled-release oral delivery system such as Concerta, have lesser likelihood of misuse or diversion.⁷⁷ It is also reasonable to consider use of a non-stimulant preparation,⁷⁸ even though nonstimulant medications are less efficacious than stimulants.⁷⁹ The prodrug formulation of dextroamphetamine, lisdexamfetamine, has a lower abuse potential than other stimulants and thus may be considered.^{80,81} However, physicians should be aware that any psychoactive medication can be misused. As for all patients, it is important to carefully monitor medication adherence.

A special circumstance occurs when a pediatrician prescribes stimulant medications for college students and older patients living away from home. A treatment plan should document how medication will be prescribed and how frequently the patient is expected to return for follow-up visits with the pediatrician. Medication administration by a student health staff member or keeping medications in a small medication safe may reduce diversion or theft. Follow-up visits should include self-report of medication efficacy, adverse effects (appetite, abdominal symptoms, headaches, and sleep disturbance) and screening for medication misuse, abuse, or diversion. The patient's responses should be documented in the medical record. Reports or suggestions of new physical or mental health symptoms require reevaluation.

SUMMARY

ADHD is a common neurobehavioral disorder of childhood, and individuals with ADHD are more likely to misuse alcohol, tobacco, and other illicit

substances compared with children and adolescents without ADHD. Individuals with ADHD and co-occurring mental health conditions, such as disruptive behavior disorders or depression, are at even higher risk of developing SUDs. Appropriate treatment of ADHD symptoms with medication and behavior therapy may reduce the risk of development of SUDs. Primary care providers should seek to identify and treat ADHD to prevent the development of SUDs. However, the recommended first-line medication therapy for ADHD is stimulant medications, which themselves pose a risk of misuse, diversion, and abuse. Therefore, an important part of ADHD treatment and stimulant medication management

includes screening for SUDs and providing anticipatory guidance around the appropriate and safe use of stimulant medications. Individuals with co-occurring ADHD and active SUDs require a careful, individual risk/benefit assessment regarding the safety of prescribing a stimulant medication. Longer acting preparations of stimulant medication, the prodrug formulation of dextroamphetamine, and non-stimulant medications for ADHD all have lower abuse potential than short-acting preparations of stimulant medication and, thus, their use should be strongly considered if there is a high risk of misuse, diversion, or abuse of stimulant medications.

Child life programs are an important component of pediatric hospital-based care to address the psychosocial concerns that accompany hospitalization and other health care experiences. Child life specialists focus on the optimal development and well-being of infants, children, adolescents, and young adults while promoting coping skills and minimizing the adverse effects of hospitalization, health care, and/or other potentially stressful experiences. Using therapeutic play, expressive modalities, and psychological preparation as primary tools, in collaboration with the entire health care team and family, child life interventions facilitate coping and adjustment at times and under circumstances that might otherwise prove overwhelming for the child. Play and developmentally appropriate communication are used to: (1) promote optimal development; (2) educate children and families about health conditions; (3) prepare children and families for medical events or procedures; (4) plan and rehearse useful coping and pain management strategies; (5) help children work through feelings about past or impending experiences; and (6) establish therapeutic relationships with patients, siblings, and parents to support family involvement in each child's care. *Pediatrics* 2014;133:e1471–e1478

CHILD LIFE PROGRAMS

During the 1920s and 1930s, early hospital play programs were initiated at several children's hospitals, including Mott Children's Hospital, Babies and Children's Hospital of Columbia Presbyterian, and Montreal Children's Hospital. In 1955, Emma Plank, under the direction of Dr Frederick C. Robbins (Nobel Laureate), developed the first Child Life and Education division at Cleveland City Hospital. Plank is considered a founding "mother" of the profession, and her landmark publication, *Working With Children in Hospitals*,¹ served to educate many about the unique needs of children in the health care setting.

Today, hospitals specializing in pediatric care routinely include child life programs, with more than 400 programs in operation in North America.² Child life services are recommended and offered to varying degrees in community hospitals with pediatric units, ambulatory clinics, emergency departments (EDs), hospice and palliative care programs, camps for children with chronic illness, rehabilitation settings, and some dental and physician offices.^{3–7} In cases of hospitalized or ill adults, certified child life specialists (CCLSs) may be consulted to work with children of adult patients, particularly in end-of-life cases, trauma, and critical care. Child life programs are not

unique to North America; similar programs can be found in other countries such as the United Kingdom, Japan, Kuwait, the Philippines, South Africa, Serbia, New Zealand, and Australia.²

The provision of child life services is a quality benchmark of an integrated patient- and family-centered health care system, a recommended component of medical education, and an indicator of excellence in pediatric care.^{8–10} An experimental evaluation of 1 child life program model showed that child life interventions resulted in less emotional distress, better overall coping during the hospital stay, a clearer understanding of procedures, and a more positive physical recovery as well as posthospital adjustment for children enrolled.¹¹ Patients spent less time on narcotics, the length of stay was slightly reduced, and parents were more satisfied. Other studies have found that child life interventions play a major role in calming children's fears and result in higher parent satisfaction ratings of the entire care experience.^{12,13}

There are a number of variables to consider in identifying adequate child life staff-to-patient ratios. Although a ratio of 1 full-time CCLS to 15 inpatients¹⁴ is useful as a guideline, a number of factors should influence specific staffing allocations. Generally speaking, child life services should be available to meet identified patient or family needs 7 days a week. In hospitals with very small pediatric units and low outpatient volume, 1 CCLS may provide services in both the inpatient and outpatient areas, including consultation services to the ED. In hospitals with high-volume pediatric emergency services, more than 1 CCLS is generally required to enable 7-day coverage of the ED. In larger hospitals, 1 or more CCLSs are typically assigned to each inpatient unit or outpatient area, including standing and/or rotating schedules to provide weekday, evening, and week-

end coverage. In any case, staffing plans should be sufficient to meet fluctuations in anticipated and unanticipated staff absences, seasonal swings in patient census, and nonclinical community activities (eg, increased visits and in-kind donations during the holiday season, variations in individual patient and family needs).

Child variables (temperament, coping style, and cognitive abilities), family variables (parental anxiety, presence, and involvement), and diagnosis/treatment variables (the number of invasive procedures) are known to affect psychosocial vulnerability and thus influence the child's particular child life intervention needs.¹⁵ A combination of psychosocial risk assessment, medical/treatment variables (eg, the proportion of patients with isolation precautions, the volume of patient/family teaching needs), and the time requirements associated with particular interventions directly affect operational staff-to-patient ratios in both inpatient and outpatient settings.^{16,17} Table 1 lists variables that typically require child life interventions of greater frequency, duration, or complexity, thus influencing effective CCLS-to-patient ratios.

The credentials of a CCLS currently include the minimum of a bachelor's degree in child life, child development, or a closely related field; the successful completion of a 480- to 600-hour child life internship under the supervision of a CCLS; and passing a standardized certification examination.^{18,19} Advanced degrees in child life

are also available, and CCLSs often develop particular areas of expertise related to the patient populations they serve.

In some settings, child life services are augmented by child life assistants (or activity coordinators or child life technicians). Child life assistants are typically required to have core college coursework, such as an associate's degree in child development, and experience with children in group settings. They generally focus on the "normalization" of the health care experience, providing play activities, coordinating special events (eg, community visitors, holiday celebrations), and maintaining the playroom environment. Both CCLSs and child life assistants actively participate in the orientation, training, and supervision of volunteers, thereby contributing to volunteer effectiveness, satisfaction, and retention. This collaboration enables the CCLS to conduct an assessment and delegate as appropriate, allowing patients with varying degrees of psychosocial vulnerability and activity levels to be supported by the team member whose skills and knowledge are most closely aligned with patient/family needs. Although volunteers are a valuable supplement, they can never be considered an adequate replacement for trained/certified professionals.

CCLSs are part of an interdisciplinary, patient- and family-centered model of care, collaborating with the family, physicians, advance practice providers, nurses, social workers, and

TABLE 1 Factors Necessitating or Supporting a Lower Ratio of Patients to CCLSs

- High volume of patient-family teaching needs (eg, surgeries and other medical procedures), especially when combined with high patient turnover rate
- High proportion of patients requiring 1-on-1 interventions (eg, isolation rooms, ventilator-dependent patients, examination/treatment room interventions, critical care units)
- Multiple simultaneous needs (eg, ED during peak hours)
- Frequent time-consuming demands (eg, support during lengthy medical procedures, end-of-life support)
- Significant nonclinical demands, such as supervision of child life students, representing child life on hospital committees, public relations and marketing activities, and other administrative duties

other members of the health care team to develop a comprehensive plan of care. Child life contributions to this plan are based on the patient's and family's psychosocial needs, cultural heritage, and responses to the health care experience. For example, child life specialists can participate in the care plan by teaching a child coping strategies for adjusting to a life-changing injury, promoting coping with examinations for alleged abuse, assisting families in talking to their children about death, facilitating nonpharmacologic pain management techniques, and communicating the child's developmental and individual needs and perspective to others. These interventions are most effective when delivered in collaboration with the entire health care team.

THE THERAPEUTIC VALUE OF PLAY

Play is an essential component of a child life program and of the child life professional's role. In addition to play's developmentally supportive benefits and as a normalizing activity for children and youth of all ages, it is particularly valuable for children who are anxious or struggling to cope with stressful circumstances.²⁰ Erikson writes, "To play out is the most natural auto-therapeutic measure childhood affords. Whatever other roles play may have in the child's development . . . the child uses it to make up for defeats, sufferings, and frustrations."²¹

Play in the health care setting is adapted to address unique needs based on developmental level, self-directed interests, medical condition and physical abilities, psychosocial vulnerabilities, and setting (eg, bedside, playroom, clinic). Play as a therapeutic modality, including health care play or "medical play," has been found to reduce children's emotional distress and help them cope with medical experiences.²² Research has shown that physiologic

responses, such as palm sweating, excessive body movement, tachycardia, and hypertension, can be reduced with therapeutic play interventions.²³

Play can be adapted to address the developmental and psychosocial needs of patients in every pediatric age group. For example, infants and toddlers benefit from exploratory and sensorimotor play, and preschool-aged children enjoy fantasy play and creative art activities.²⁴ Opportunities for parents to engage in play activities with their young children are beneficial to both patient and family, alleviating some feelings of helplessness in parents and assisting in the child's hospital adjustment.²⁵ School-aged children and adolescents seek play that contributes to feelings of mastery and achievement, which is one reason video games are so popular with this age group.²⁶ Patients in this age group also benefit from activities that allow them to maintain relationships with peers and establish new connections through, for example, online networking and the availability of teen activity rooms in the hospital setting.²⁷

Auxiliary programs, such as animal-assisted therapy, infant massage instruction, use of therapeutic clowns, performing arts, and artist-in-residence programs, often used in conjunction with child life services, provide additional outlets for patients of all ages and their families.^{28,29} Live, interactive programming, such as hospital bingo or patient-produced videos (broadcast over a closed-circuit television system), can be a particularly effective way to engage patients restricted to their rooms for infection control or medical reasons. Expressive therapies, such as those provided by distinctly certified play therapists, music therapists, and art therapists, can be offered to complement child life programs and to provide support for particularly vulnerable patients.^{30,31}

PSYCHOLOGICAL PREPARATION

Preparing children for hospitalization, clinic visits, surgeries, and diagnostic/therapeutic procedures is another important element of a child life program. It is estimated that 50% to 75% of children develop significant fear and anxiety before surgery, with recognized risk factors such as age, temperament, baseline anxiety, past medical encounters, and parents' level of anxiety.³² Children's anxiety in the peri-operative environment is associated with impaired postoperative behavioral and clinical recovery, including increased analgesic requirements and delayed discharge from the recovery room.³³ More than 50 years of research and experience support 3 key elements of the preparation process: (1) the provision of developmentally appropriate information; (2) the encouragement of questions and emotional expression; and (3) the formation of a trusting relationship with a health care professional.³⁴ A recent systematic review of preparation effectiveness evidence concluded that children who were psychologically prepared for surgery experienced fewer negative symptoms than did children who did not receive formal preparation. In addition to reducing anxiety and providing a more positive experience for the patient and family, research demonstrates that preparation and coping facilitation interventions decrease the need for sedation in procedures such as MRIs, resulting in lower risks for the child and cost savings in personnel, anesthesia, and throughput-related expenses.^{35–37}

Preparation techniques, materials, and language must be adapted to the developmental level, personality, and unique experiences of the child and his or her family. Learning is enhanced with "hands-on" methods versus exclusively verbal explanations. Photographs, diagrams, tours of surgical or

treatment areas, actual and pretend medical equipment, and various models (eg, dolls, puppets) are used to reinforce learning and actively engage the child.^{32,38} Interpreter services are used as appropriate to ensure understanding in patients or families who do not speak English or for whom English is a second language. Most parents have a strong desire for comprehensive information about their child's care and should be included in the preparation process. In cases in which children demonstrate avoidant preferences or when preparation before the event is not possible, the CCLS's focus may change from that of imparting information to other supportive strategies, such as teaching behavioral coping skills and preparing parents to support their child during a medical procedure.

PAIN MANAGEMENT AND COPING STRATEGIES

When combined with preparation and appropriate pharmacologic interventions, nonpharmacologic strategies for pain and distress management have proven successful in terms of patient/family experience, staff experience, and cost-effectiveness.^{13,39–40} Strategies such as swaddling, oral sucrose, vibratory stimulation, breathing techniques, distraction, and visual imagery have been shown to decrease behavioral distress and pain experience in children during invasive medical procedures.^{41–43} In addition to advocating for the appropriate use of analgesics, CCLSs are often directly involved in the utilization of nonpharmacologic pain management techniques and coaching or supporting patients and families before and/or during distressing medical procedures.^{44,45} They can also provide valuable education and training to nursing, medical, and other personnel and students, thus supporting health care team member competencies in the

provision of developmentally appropriate, psychosocially sound care.^{46,47} Multifaceted institution-wide protocols such as the “Ouchless Place” and other similar programs incorporate the standard utilization of both pharmacologic and nonpharmacologic techniques, preparation of patient and family, environmental considerations, and training of all health care team members.^{48,49} Research has demonstrated that children are less fearful and distressed when positioned for medical procedures in a sitting position, rather than supine.⁵⁰ CCLSs are often involved in facilitating the use of “comfort holds”: techniques for positioning children in a parent/caregiver's lap or other comforting position. In addition to reducing the child's distress and gaining his or her cooperation, these techniques generally require fewer staff to be present in the room, facilitate safe and effective accomplishment of the medical procedure, decrease parent anxiety, and increase parent satisfaction.^{51–53} With a goal to limit the use of papoose boards and alleviate the practice of multiple staff members holding a child down, these techniques provide a viable and more humane alternative in most cases.

CCLSs may also develop “comfort kits” for use in treatment areas to include age-appropriate distraction items such as bubbles, pop-up and sound books, light-up toys, and other visual or auditory tools.⁵⁴ There is emerging evidence that mobile devices can be effective in minimizing patient perceptions of pain and anxiety during distressing medical procedures.⁵⁵ CCLSs can also advocate for a more welcoming environment in treatment and examination rooms on pediatric units as well as outpatient settings. Their background and training are helpful in designing settings that are appropriately stimulating, nonthreatening, and interactive.

FAMILY SUPPORT

The presence and participation of family members is a fundamental component of patient- and family-centered care and has a significant positive effect on a child's adjustment to the health care experience.⁵⁶ When parents or other family members are highly anxious about the child's illness or diagnostic and treatment regimens, such anxiety is easily transmitted to the patient.⁵⁷ CCLSs help facilitate the family's adjustment to the child's illness and health care experience. They can help family members understand their child's response to treatment and support caregiving roles by promoting parent/child play sessions and sharing strategies for comforting or coaching the child during medical procedures.

Siblings of pediatric patients present with their own unique anxieties and psychosocial needs, needs that are often not assessed or addressed. Siblings, much like children of adult patients, can be helped to comprehend a family member's illness via therapeutic play and educational interventions or by offering support during hospital visits, including critical care and end-of-life situations.⁵⁸ CCLSs are often involved in providing grief support or legacy activities, such as hand molds or memory boxes for siblings and other family members in the event of the death of pediatric or adult patients.

RECENT DEVELOPMENTS IN CHILD LIFE SERVICES

The scope of child life programs has developed beyond pediatric inpatient medical–surgical settings to include outpatient and other areas in which child life expertise can be effectively applied to support children and families in stressful situations. The provision or expansion of dedicated child life programming in areas such as emergency services, surgery, imaging, specialty care clinics, dialysis centers,

palliative care, and neonatal intensive care has become more prevalent.^{59,60} The increase in patients diagnosed with autism spectrum disorders has presented opportunities for child life specialization in supporting this population in the medical setting.⁶¹

Over the past several years, child life programs have adapted to the great variety of patients and illnesses seen in pediatrics. Younger, less mobile patients who have more complex medical conditions may need greater individualization of care from the CCLS, for example, when group interaction is not possible. Activities that enable social interaction, such as Internet connectivity and closed-circuit television programming, are particularly helpful for patients who are isolated for infection control or confined for monitoring reasons. Given the increasing survival rate of patients with cystic fibrosis, cardiac conditions, and other chronic illnesses, more teenagers and young adults face the challenging transition to adult health care.⁶² Acknowledging team goals to normalize the transition process and address patient and family anxieties or questions, CCLSs can assist in this transition by providing education and helping patients to communicate their needs, fears, hopes, and expectations.^{63–65}

Although evidence supports the value of child life programs, financial pressures in many health care settings have threatened the growth and sustainability of this essential service. Recent literature has demonstrated the benefits of child life interventions in reducing sedation-related costs,³⁵ and additional research is underway to further evaluate the cost-effectiveness of child life services.

Child life programs are recognized as contributing to a culture of patient- and family-centered care as well as to customer satisfaction measures, increasingly important from an incentive-

based reimbursement and accreditation standpoint as well as marketing and public reporting of outcomes. Child life and ancillary services, such as creative arts therapy, often attract a segment of the population that may otherwise not be inclined to provide philanthropic support to a hospital. Child life leaders are regularly involved in community outreach, public relations, and funding of development activities.

ADDITIONAL CONSIDERATIONS

Child life services contribute to an organization's efforts to meet the standards set forth by The Joint Commission with regard to effective communication, patient- and family-centered care, age-specific competencies, and cultural competence.⁶⁶ The CCLSs' psychosocial and developmental expertise and their keen awareness of the benefits of patient- and family-centered care provide a useful perspective at the systems level. Child life representation is often incorporated into hospital committees, such as ethics, patient/family satisfaction, safety, environmental design, and bereavement. In many cases, child life professionals provide leadership for activities such as patient and/or family advisory councils and hospital-wide staff education.

Child life expertise has applications beyond conventional hospital care. Interventions can help children transition back to their home, school, community, and medical home.*⁶⁷

*The American Academy of Pediatrics (AAP) believes that the medical care of infants, children, and adolescents ideally should be accessible, continuous, comprehensive, family centered, coordinated, compassionate, and culturally effective. It should be delivered or directed by well-trained physicians who provide primary care and help to manage and facilitate essentially all aspects of pediatric care. The physician should be known to the child and family and should be able to develop a partnership of mutual responsibility and trust with him or her. These characteristics define the "medical home."

CCLSs often collaborate with local school districts to arrange hospital or homebound education, and hospital-based teachers may be incorporated into child life program administration.

For hospitals or other health care settings considering the initiation or expansion of child life services, the Child Life Council offers a consultation service to support existing program review and development, new program start-up, interdisciplinary education, and written standards of care.⁶⁸ In community hospital settings with few pediatric beds and minimal pediatric outpatient or ED visits, the provision of full-time child life services may not be financially feasible. In such cases, it is recommended that part-time or consultative services of a CCLS be obtained to assist in the ongoing education of staff, students, and volunteers as well as to advise on a psychosocially sound, developmentally appropriate, patient- and family-centered approach to care.

CONCLUSIONS

Child life services improve quality and outcomes in pediatric care as well as the patient and family experience. Although more research is needed, there is evidence that child life services help to contain costs by reducing the length of stay and decreasing the need for sedation and analgesics. Patient/family satisfaction data and interdisciplinary team member feedback further confirm the positive effects of child life programs on children, families, and staff. It remains essential for child life services to adapt and grow with the changing health care delivery system in support of the highest possible quality of care for children and their families.

RECOMMENDATIONS

1. Child life services should be delivered as part of an integrated patient- and family-centered model of

care and included as a quality indicator in the delivery of services for children and families in health care settings.

2. Child life services should be provided directly by certified child life specialists in pediatric inpatient units, emergency departments, chronic care centers, and other diagnostic/treatment areas to the extent appropriate for the population served. In hospitals with a small number of inpatient or outpatient pediatric visits, ongoing consultation with a certified child life specialist is recommended to educate health care team members and support developmentally appropriate, patient- and family-centered practice.
3. Child life services staffing should be individualized to address the needs of specific inpatient and outpatient areas. Child life specialist-

to-patient ratios should be adjusted as needed for the medical complexity of patients served, including psychosocial and developmental vulnerability as well as family needs and preferences.

4. Child life services should be included in the hospital operating budget as an essential part of hospital-based pediatric care. Advocacy for financing of child life services should occur at the facility, community, state, and federal levels.
5. Additional research should be conducted to evaluate the effects of child life services on patient care outcomes, including patient and family experience/satisfaction, staffing ratios, throughput, and cost-effectiveness.

Children's Health Insurance Program (CHIP): Accomplishments, Challenges, and Policy Recommendations

.....

- *Policy Statement*

POLICY STATEMENT

Children's Health Insurance Program (CHIP): Accomplishments, Challenges, and Policy Recommendations

abstract

FREE

Sixteen years ago, the 105th Congress, responding to the needs of 10 million children in the United States who lacked health insurance, created the State Children's Health Insurance Program (SCHIP) as part of the Balanced Budget Act of 1997. Enacted as Title XXI of the Social Security Act, the Children's Health Insurance Program (CHIP; or SCHIP as it has been known at some points) provided states with federal assistance to create programs specifically designed for children from families with incomes that exceeded Medicaid thresholds but that were insufficient to enable them to afford private health insurance. Congress provided \$40 billion in block grants over 10 years for states to expand their existing Medicaid programs to cover the intended populations, to erect new stand-alone SCHIP programs for these children, or to effect some combination of both options. Congress reauthorized CHIP once in 2009 under the Children's Health Insurance Program Reauthorization Act and extended its life further within provisions of the Patient Protection and Affordable Care Act of 2010. The purpose of this statement is to review the features of CHIP as it has evolved over the 16 years of its existence; to summarize what is known about the effects that the program has had on coverage, access, health status, and disparities among participants; to identify challenges that remain with respect to insuring this group of vulnerable children, including the impact that provisions of the new Affordable Care Act will have on the issue of health insurance coverage for near-poor children after 2015; and to offer recommendations on how to expand and strengthen the national commitment to provide health insurance to all children regardless of means. *Pediatrics* 2014;133:e784–e793

LEGISLATIVE BACKGROUND AND EVOLUTION OF THE CHILDREN'S HEALTH INSURANCE PROGRAM

The Children's Health Insurance Program (CHIP) emerged as a consequence of previous policy experiences and political realities that characterized the late 1990s. The combination of successful Medicaid expansions in the late 1980s and early 1990s and the failure of the Clinton health reform proposals of the mid-1990s prepared the stage for both Democrats and Republicans to cooperate in fashioning an extension of health insurance for 10.1 million uninsured near-poor

children that would not establish a new entitlement program.¹ The resulting legislation, Title XXI of the Social Security Act (42 USC 7, §§1397aa–1397mm), inserted a provision into the Balanced Budget Act of 1997 (Pub L No. 105–33, 111 Stat 251) that encouraged states to establish programs to provide health insurance to noncovered children who lived in families with incomes up to 200% of the federal poverty level. The act incorporated specific design elements that made it more attractive to state governments, which would bear a large responsibility for its implementation. Using a level of federal matching funds in excess of that provided to the Medicaid program (70% of the cost of the program, on average, compared with 57% for Medicaid),² states were enabled to craft programs that were either extensions of their existing Medicaid programs or new stand-alone programs or a combination of both.³ The stand-alone programs were permitted to include cost sharing and premiums, and their benefit packages could differ from what was available in Medicaid, whereas the Medicaid extension programs were required to adhere to the traditional Medicaid package.

The new legislation budgeted \$40 billion for the 10 years of the program as a capped block grant to states rather than as an entitlement. To prevent states from shifting children from Medicaid to a program with greater federal cost sharing, the law mandated a maintenance-of-effort obligation and strict screening of Medicaid eligibility. To discourage crowd-out from the commercial insurance pool, the law also limited availability of the program to individuals without other forms of potential coverage and imposed waiting periods before patients could access the program after losing private coverage.⁴

As states were establishing their programs in the early years of CHIP, the

federal allotments exceeded state expenditures. By 2000, however, every state and territory as well as the District of Columbia had established its own program, so that by the middle part of that decade, states were beginning to find that their expenditures were outstripping the federal block grants allocated to them. To remedy such shortfalls in 2006 and again in 2007, Congress appropriated increased funds for the program above the original 1997 allocation.

At the 10-year mark, despite considerable progress in coverage for near-poor children, CHIP continued to confront 3 issues: provision of sufficient financing for the states to meet the needs of the intended population; adequate outreach, enrollment, and retention efforts for eligible children; and a perceived need to focus more on access and the quality of care for those covered.⁵ The 110th Congress attempted to reauthorize the program in 2007, but despite passage in both houses of Congress, the legislation was twice vetoed.⁶ In the absence of long-term funding, the Medicare, Medicaid, and CHIP Extension Act of 2007 (Pub L No. 110–173) was enacted to appropriate funds at the 2007 level to cover the costs of the program for 2008 through March 31, 2009.⁷

After the 2008 presidential elections, the new administration set the extension of CHIP as an important early legislative priority. President Obama signed the Children's Health Insurance Program Reauthorization Act of 2009 (CHIPRA; Pub L No. 111-3) into law on February 4, 2009,⁸ with several specific policy goals in mind. The law increased appropriations for the program in acknowledgment of the shortfalls that states had been experiencing under the previous funding levels and extended the life of the program through 2013. In addition, it included a number of funding mechanisms, such as

Express Lane eligibility and state bonuses for reaching enrollment goals that were intended to extend Medicaid and CHIP coverage to millions of additional uninsured children and to increase outreach to many who lacked coverage despite being eligible for these programs. Finally, it improved benefits, enhanced data collection, and created a new emphasis on measuring the quality of care children received.⁹

One year later with the passage of the Patient Protection and Affordable Care Act (ACA; Pub L No. 111–148 [2010]),¹⁰ other modifications of CHIP came online: in particular, the ACA extended the funding for CHIP by another 2 years, through September 31, 2015. In addition, because the ACA enabled all citizens younger than 65 years with household incomes less than 133% of the federal poverty level (\$31 322 for a family of 4 in 2013, to which a 5% income disregard will be applied when considering eligibility)* to become eligible for Medicaid effective January 2014 (if, in view of the June 2012 Supreme Court decision, their state of residence agrees to participate in the Medicaid expansions),¹¹ the ACA anticipated that some children older than 6 years previously covered by a stand-alone CHIP plan would transition into Medicaid. In such cases, the ACA provides states the enhanced CHIP matching rates for those individuals. Furthermore, beginning in fiscal year 2016, the federal CHIP matching rate is slated to increase by 23 percentage points to an average of 93%. Finally,

*To determine income eligibility for Medicaid under the ACA, the statute references an individual's modified adjusted gross income and adds a standard 5% "income disregard," making the effective threshold for eligibility 138% of the federal poverty level. See "Determining Income for Adults Applying for Medicaid and Exchange Coverage Subsidies: How Income Measured With a Prior Tax Return Compares to Current Income at Enrollment" from The Kaiser Family Foundation Focus on Health Reform at <http://www.kff.org/healthreform/upload/8168.pdf>.

although the ACA extended authority for CHIP through 2019 and included maintenance-of-effort requirements for eligibility, identification, and enrollment of children in Medicaid and CHIP through that time period, it provided federal CHIP allotments to finance the program only through fiscal year 2015.¹²

ACCOMPLISHMENTS OF CHIP

Insurance Coverage

Incontrovertible evidence demonstrates that the CHIP program increased insurance coverage to its intended population above what it would have been in the absence of the program (see Fig 1). Although at the time of CHIP's enactment in 1997, states already had, under the existing Medicaid program, the option of expanding coverage for children in families up to 200% of the federal poverty level, only 6 states had availed themselves of this opportunity.¹³ From the enactment of CHIP in 1997 to 2011, enrollment has grown from under 1 million to 5.3 million children.^{14,15} Furthermore, the enactment of CHIPRA has had important spillover effects on the enrollment of eligible children into Medicaid so that the combined impact on the rate of uninsurance among children has been significant.¹⁶

Although the percentage of US children with private employer-sponsored health insurance decreased from 66.2% to 53.0% over this time, the proportion covered by public insurance, including Medicaid or CHIP, increased from 21.4% to 42.0% so that the total percentage of uninsured US children decreased from 13.9% to 6.6% at a time when the uninsurance rates among adults were increasing.^{17,18} Moreover, the reductions in uninsurance were concentrated among the population of children in families at or below 200% of the federal poverty level. The percentage of children covered by employer-sponsored insurance in this group fell from 34.4% to 24.9%, whereas the percentage of those on Medicaid or CHIP increased from 41.3% to 60.4% so that the uninsurance rate among these children decreased from 24.6% to 15.3% over this period.¹⁷ Beyond extending coverage to more children, specific provisions in CHIPRA made it mandatory for stand-alone CHIP programs to include dental coverage for children (section 2103(c)(5))¹⁹ and to cover mental health services and substance abuse services on parity with medical and surgical coverage.

Even subsequent to the 2008 recession, CHIP continues to increase its enrollment, although at a slower rate than

before. Some have speculated that this slowdown is partially attributable to the migration of some children from CHIP to Medicaid as parents have lost employment.¹⁵ How much of the decline in private insurance coverage can be attributable to enrollment in the CHIP program has generated intense debate in the "crowd-out" literature, but a recent review of the evidence noted that only 4 of 22 pertinent studies examined found statistically significant crowd-out effects.²⁰ Among those who did find evidence of crowd-out, the magnitude of the estimates varied widely from 0% to 50% depending upon the underlying assumptions of their statistical model.²¹

Access to Care

For children enrolled in CHIP programs, most researchers, with occasional dissenting voices,²² have found that access to care and utilization of primary and preventive care appear to improve after enrollment.²⁰ Although methodologic challenges abound in trying to arrive at robust estimations in this regard,²³ evaluations conducted in individual states^{24–26} or across combinations of states^{16,27} have found, in general, that enrollees report improvements in having a usual source of care, in completing visits to physicians or dentists, and in having fewer unmet health needs after enrollment. Furthermore, some observers cite evidence indicating that racial/ethnic disparities in access and utilization detectable among new CHIP participants before they enrolled were either eliminated or greatly reduced after enrollment.²⁸ Other researchers have reported that the benefits of CHIP enrollment with respect to reductions in unmet needs are greater for children with chronic health conditions.²⁹ Finally, older children (older than 13 years) from low-income families who had not been eligible for public health insurance coverage before the enactment of CHIP appear to have had disproportionately greater increases in the

FIGURE 1

Health insurance rates for children in the United States, 1997–2012. Source: National Center for Health Statistics, 2013.¹⁸

likelihood of a physician visit and greater declines in rates of uninsurance as a result of the enactment of this program, when compared with younger children from poor and near-poor households.³⁰

Health Status and Quality of Care

Unambiguous evidence of the effects of CHIP on improvements in children's health status as measured either by mortality rates, morbidity, improved functional status, or parent-reported health assessment is more difficult to substantiate for a variety of reasons.²³ Some of the studies^{31,32} reported benefits of improved publicly funded health insurance lump effects of Medicaid with those of CHIP, even though they apply to different populations and may have been studied in different time periods. Despite these caveats, there are suggestions that enrollment in CHIP may have had positive effects on certain measures of health and well-being among participants.^{33,34}

Finally, over and apart from the direct effects that CHIP has had on the access, utilization, and health status of near-poor children, the provisions in CHIPRA that focus on the quality of care delivered to children are of signal importance. A major innovative element of CHIPRA was the incorporation of quality child health measurement standards, monitoring capabilities, and reporting requirements for states in section 401a of the statute.³⁵ The legislation established a mechanism by which the Centers for Medicare and Medicaid Services collaborated with the Agency for Healthcare Research and Quality to identify an initial core set of child health quality measures on which states could voluntarily agree to report.^{35,36} CHIPRA also allocated a total of \$100 million in awards to 18 states to encourage creation of quality demonstration projects. Since the law's enactment, the US Department of Health

and Human Services has been required to report on the quality of care received by children covered by Medicaid and CHIP.

PROBLEMATIC ISSUES FOR CHIP

CHIP and the ACA

Whereas it is important to acknowledge the signal achievements of the ACA in extending health insurance coverage, reforming practices in the health insurance market, and incentivizing opportunities to moderate health care costs, it is equally necessary to be alert to aspects of the new law that raise concerns regarding the future of CHIP. Many of these concerns emerge only from a detailed understanding of specific features of the legislation and are outlined as follows:

- First and foremost is the question of ongoing funding particularly in view of provisions of the ACA that preserve federal funding for CHIP only through 2015. After this date, it is not certain whether the program will be continued or whether some subset of children currently covered under CHIP who satisfy other eligibility criteria will be expected to transition into the new health insurance marketplaces, whereas others will be left without coverage entirely. This latter scenario may constitute an inferior outcome, even for children who do qualify to be covered by the marketplaces. At least 1 comparative analysis in 17 states found that the benefits and cost-sharing levels in existing CHIP programs were superior to those in the marketplaces.³⁷
- Second, initial experience with federal- and state-sponsored insurance marketplaces suggest that network restrictions limiting access to children's hospitals and certain subspecialists constitute a significant cost-containment strategy in many geographic areas. These restrictions

within the ACA framework are less beneficial to children compared with what they currently experience in CHIP.

- Third, the majority Supreme Court decision upholding the ACA but rendering state participation in the new Medicaid expansions optional¹¹ creates further inconsistencies that might leave certain poor older adolescents ineligible for any public funding in states that refuse to accept the new Medicaid expansions.³⁸ Even if the ACA is implemented such that all states opt to embrace the Medicaid expansions, a considerable number of children will find themselves in situations where their coverage is with a public plan, whereas their parents either have no coverage because they do not qualify for Medicaid under the proposed expansions or have different coverage from their children because they are in one of the marketplace plans, hence complicating coordination of benefits within the family.³⁹
- Fourth, another distinct disadvantage for children under the ACA involves the calculation of eligibility for premium tax credits under the law. The Internal Revenue Service has ruled that those whose premiums cost more than 9.5% of their gross adjusted income are eligible for tax credits from the federal government, but only the cost of an individual policy is taken into account in making this calculation. Because family coverage is more expensive than individual coverage, parents with children may find themselves paying more than 9.5% of their income to obtain coverage but being nevertheless ineligible for these credits (a feature known as the "kid glitch").
- Fifth, although the ACA permits children up to the age of 26 years

to remain on their parents' policies, this benefit does not extend to grandchildren (ie, children who might be born to these young adults).

- Finally, although provisions in the ACA have made redistribution of funds among states more responsive to the differential shortfalls in funding that emerge across different states over time, the block grant nature of the CHIP makes it difficult for all states to adjust their programs to the changing needs and numbers of near-poor children. This situation could become critical if future economic downturns render more families eligible for a program that has a cap on its total spending.

Enrollment and Retention

In addition to the concerns regarding future funding, the current program has yet to address other issues of enrollment and retention. There are now estimated to be 7.7 million children enrolled in the CHIP program, of whom 70% are in stand-alone programs.³ Despite the remarkable success of Medicaid and CHIP at reducing uninsurance among children from low-income families, an estimated 7.5 million children in the United States still remain uninsured, of whom 60% to 70% are thought to be eligible for public insurance of some kind.¹² Identifying those children and increasing the rate at which they enroll in CHIP is an ongoing challenge for the program. For children who do enroll, the rate of retention in the program is also lower than it might be. It was estimated in 2008 that 26.8% of uninsured children had been enrolled in public insurance the previous year, with 21.7% formerly enrolled in Medicaid and 5.1% enrolled in CHIP.⁴⁰ Understanding the reasons for and consequences of these dropouts, whether they result from

barriers associated with state enrollment and reenrollment policies, documentation and related concerns among immigrant parents of children born in the United States, changes in employment status, or other factors, should be a priority for the program.

Part of the advantage of CHIP has been the built-in flexibility it has afforded states with respect to its implementation, particularly among stand-alone CHIP programs rather than pure Medicaid expansions. Because states have faced differential budgetary constraints in the aftermath of the recent recession, having some leeway in how to structure benefits and set eligibility for near-poor children has been a boon to policy makers facing difficult fiscal choices at the state level. This sanctioned flexibility in the rate of CHIP implementation, the degree of cost sharing, the generosity of benefit packages, and the extensiveness of outreach to those eligible but uninsured has, in turn, resulted in considerable state-to-state variation in retention rates and in the overall benefit of the program. Provisions of the ACA will do little to modify these operational aspects of CHIP.

Physician Participation

The rates at which pediatricians have been willing to accept children covered by public health insurance programs have declined in recent years as the payment rates in these programs have generally deteriorated relative to rates associated with commercial plans. A recent report by the Government Accountability Office summarizing a national survey of pediatricians indicated that although 47% of those surveyed reported that they would accept all new Medicaid or CHIP patients, the comparable figure for privately insured patients was 79%.⁴¹ In those states that have CHIP arrangements that are Medicaid expansions (and

some states with a stand-alone CHIP program use Medicaid plans and payment rates in CHIP), rates of acceptance of CHIP patients and Medicaid patients are highly correlated. To attempt to address this concern, at least in part, provisions of the ACA (§1202) require that, for primary care providers, Medicaid payment rates be increased to 100% of those available through Medicare.^{22,42} The federal government has issued a final rule, clarifying the following: (1) that this innovation applies to primary care evaluation and management (E&M) codes 99201–99499, including pediatric services that are not traditionally provided by Medicare practitioners; (2) that they apply to Medicaid managed care plans as well as traditional fee-for-service arrangements; and (3) that they apply to services administered by or under the direction of physicians in primary care specialties or subspecialties.⁴³ This ruling is important especially because three-quarters of CHIP patients are enrolled in managed care plans³ and the payment rates for participation in these plans vary considerably on a regional basis. Most pediatricians are in a disadvantageous position when it comes to negotiating payment rates with large insurance companies that can be the sole payers in a specific geographic locale. Less encouraging is the fact that the increase in the Medicaid fee structure to achieve parity with Medicare is time delimited and is due to expire after 2014.

Pediatric Providers and the Future of CHIP

How pediatricians and pediatric subspecialists respond to the incentives provided by CHIP is a critical consideration in evaluating the program's effectiveness over time. Because payments to physicians for patients enrolled in CHIP are generally lower than payments received from commercially

insured patients, the additional insurance coverage that CHIP achieves may result in access and utilization improvements for CHIP patients, which, although laudable, are smaller than they would be were payment rates in this program commensurate with commercial insurance. Indeed, some researchers examining physician response to the program found that, although participation on the part of pediatricians increased with CHIP's introduction, the hours devoted to patient care for all patients decreased,⁴⁴ and the visits to physicians remained unchanged.⁴⁵ These empirical findings indicate that rates of physician payment for CHIP participants will continue to influence how successfully the program achieves its articulated aims. To what extent these developments have implications for the growth of the pediatric workforce in the future is also a matter of considerable importance in the medium- to long-term. Disadvantageous payment rates covering greater proportions of pediatric patients may influence the decisions of those emerging from medical school with significant financial obligations of their own to preferentially consider alternative fields of specialization.

CHIPRA and the ACA have made important contributions to the advancement of health care delivery to near-poor children in recent years and have the potential to accomplish more so in years to come. Going forward, there is a series of issues that the pediatric community must continue to monitor to preserve the advances that have been made and to expand on them where possible. The ACA has mandated that income thresholds for CHIP are to remain constant through 2019 (although the federal government has yet to appropriate funds for the program beyond 2015), but state-by-state variability in cost sharing in the form of premiums, deductibles, and

coinsurance for CHIP stand-alone programs will need to be minimized to maintain true access to health care services, especially to subspecialty care. Pediatricians and families must continue to assess vigilantly the comprehensiveness of benefit packages available under the program, because these features will also vary from state to state. Policy makers will need to set payment rates at adequate levels if a significant proportion of the pediatric community is to engage actively in the care of CHIP enrollees. All those with an interest in advancing child well-being must monitor closely eligibility and benefits for emancipated minors, for children up to 26 years of age, for foster children once they reach the age of majority, for children of undocumented immigrants, and other vulnerable populations. Finally, the relationship between CHIP and the new health care marketplaces must be clearly delineated to ensure that the benefits for children are maintained at least at the present level and that the needs of children are not overlooked as these new structures are being created.

RECOMMENDATIONS

In view of the accomplishments of the CHIP program and the changing dynamics in the health care landscape, the American Academy of Pediatrics (AAP) makes the following recommendations with respect to this program:

1. Fully fund CHIP through 2019.

- Extend the current appropriations formula beyond the 2015 date to continue comprehensive funding of CHIP through 2019.
- Support maintenance of effort for eligibility thresholds and enrollment and renewal procedures for children in CHIP through 2019.
- Maintain the enhanced federal matching rate for CHIP to

encourage states to take advantage of these funds.

- Continue the performance bonuses program beyond fiscal year 2013 to encourage states to innovate with respect to enrollment and retention policies.
 - Maintain contingency funds for states that experience funding shortfalls.
 - Strongly consider transforming CHIP from a block grant program to an entitlement for children in families with incomes less than 300% of the federal poverty level with sliding scale subsidies to eliminate the possibility of denial of coverage because of state caps on spending.
- ### 2. Expand awareness of CHIP among eligible families.
- Encourage state and local departments of health to develop culturally appropriate written and Web-based outreach materials focused on families with incomes that meet CHIP eligibility criteria, concentrating particularly on children with special health care needs.
 - Expand the availability of AAP-generated resources using plain language principles,⁴⁶ and partner with other public and private organizations to produce resources that individual pediatricians can use in their offices to encourage families to enroll in CHIP programs, when applicable.
- ### 3. Facilitate access to CHIP by eligible children.
- Mandate all states to adopt automatic coverage for newborns, and require or incentivize multi-year (5-year) continuous eligibility in Medicaid/CHIP for newborns/infants.
 - Mandate all states to adopt 12-month continuous eligibility

for children and pregnant women in CHIP and Medicaid.

- Mandate all states to automatically enroll all children participating in the Supplemental Nutrition Assistance Program into Medicaid or CHIP.
- Streamline CHIP enrollment and renewal procedures by allowing self-declared income, using passive renewal procedures, eliminating face-to-face renewal encounters, and improving communication with families regarding renewal procedures.
- Coordinate CHIP enrollment efforts with community-based programs that work to enroll uninsured patients in Medicaid, new insurance exchanges, or other appropriate sources of health insurance.
- Expand the use of technology to facilitate enrollment and renewal by the use of prepopulated forms and the expansion of Express Lane eligibility that coordinates enrollment in CHIP with eligibility or enrollment in other public support programs, such as Temporary Assistance for Needy Families (TANF), the Supplemental Nutrition Assistance Program, the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC), etc.
- Decrease or eliminate enrollment fees and eliminate “lock-out” periods after disenrollment from CHIP for failure to pay premiums.
- Eliminate waiting periods for enrollment into CHIP after loss of employer-based insurance.
- Encourage states to take advantage of the provision in ACA that enables state programs to offer CHIP enrollment to children of

state employees who qualify for the program.

- Maintain eligibility levels and performance bonuses for states that exceed CHIP enrollment targets.
 - Eliminate the discrimination against undocumented children by allowing them access to the CHIP program if they meet other eligibility criteria.
 - Encourage all states to take advantage of the option to cover documented immigrant children through provisions in the Immigrant Children Health Insurance Act provisions of the CHIPRA legislation.
 - Allow youth who are considered “lawfully present” under the Deferred Action for Childhood Arrivals (DACA) program to qualify for Medicaid, CHIP, or tax credits in the marketplace.
 - Strongly consider allowing all children, “under color of law,” regardless of citizenship status to enroll in CHIP.
 - Extend Medicaid/CHIP coverage to age 21, and extend coverage to age 26 for children with special needs.
 - Extend age-appropriate coverage to infants of mothers who are covered under the “age 26” provision.
 - Auto-enroll youth leaving the juvenile justice system into Medicaid or CHIP, and extend coverage for former juvenile justice youth up to age 26 to align with available coverage for children aging out of the foster care system.
4. Work to reconcile stipulations in CHIPRA and the ACA.
- Eliminate “premium stacking” for families in states with separate CHIP programs in which

parents are eligible to enter the newly created marketplaces so that families whose adult members enter the marketplaces are not paying separate uncoordinated premiums for children and adults.

- Require the use of family, rather than individual, premiums for calculating the percentage of income devoted to employer-sponsored health care insurance in determining who is eligible for premium tax credits under provisions of §32B(c)2(C) of the ACA; or alternatively, enable these families to choose CHIP to cover their children.
- Eliminate the 4-week gap in coverage for children transitioning from CHIP to marketplace coverage.
- Work with states to address churning of children between plans by continuing 12-month continuous enrollment and requiring insurers to allow continuation of a child's medical home irrespective of payer (see recommendations on churning in the Medicaid and CHIP Payment and Access Commission's March 2013 Report to Congress, pages 26–43⁴⁷).
- Encourage all states to opt into the Medicaid expansions available through the ACA to cover more parents, thereby increasing the likelihood that their children will acquire health insurance.
- Allow special consideration to be given to families with unique custody circumstances, such as those with parents who are enrolled in marketplaces but whose children are eligible for CHIP, families of foster children, or those with joint custody, nonparental guardianship, or undocumented

parents where knowledge of potential coverage options for children may be limited.

5. Maximize comprehensive coverage and affordability for children in CHIP.
 - Require the adoption of state-level requirements that insurance packages contracted by stand-alone CHIP programs meet essential health benefits packages that also adhere to *Bright Futures* guidelines⁴⁸ with respect to the provision of primary preventive, screening, diagnostic, interventional, subspecialty, dental, surgical, mental health, and palliative care and include all benefits outlined in the AAP policy statement "Scope of Health Care Benefits for Children From Birth Through Age 26."⁴⁹
 - Require/reinforce a defined dental, vision, mental health, and habilitative service benefit for children.
 - Require the National Association of Insurance Commissioners (NAIC) definition of habilitation as a required benefit for all plans.
 - Collect information on compliance with parity in mental health benefits in CHIP plans.
 - Consider the extension of eligibility for the Vaccines for Children Program to all children in non-Medicaid CHIP programs in all states.
 - Maintain the prohibition against any cost sharing for preventive care services, including immunizations, in stand-alone CHIP programs.
 - Prohibit the use of any cost-sharing arrangements in CHIP that shift costs to pediatricians, hospitals, or other health care providers.
- Strengthen and clarify tracking of all out-of-pocket payments across medical and dental benefits in CHIP to ensure that families do not pay beyond 5% of household income.
6. Support the quality measurement provisions incorporated into CHIPRA.
 - Establish incentives to encourage states to report on the full core measure set, and eventually require standardized reporting by states of all quality measures in the pediatric core set.
 - Establish an advisory panel regarding pediatric quality.
 - Sustain and extend support for CHIPRA-funded Centers of Excellence to develop pediatric measures.
 - Analyze effectiveness of the pediatric electronic health record format and work to support the development of a unified pediatric electronic health record that could be widely adapted in multiple practice settings.
 - Encourage the development, dissemination, monitoring, and reporting on a set of child-specific quality measures beyond the initial core set of 24 metrics that will enable policy makers, practitioners, patients, and families to compare outcomes across practice settings, regions, and insurance plans.
 - Allow CHIP case-mix calculations for HITECH Act electronic health records incentive payments.⁵⁰
 - Support ongoing funding at the National Institutes of Health and other federal agencies for the development, dissemination, implementation, and evaluation of these pediatric-specific quality measures.
- Encourage specifically, direct comparisons wherever possible in quality measures, outcome evaluations, and cost-effectiveness between CHIP enrollees and children who end up enrolled in market-place insurance plans.
- Build on existing state demonstration grants to continue and expand a focus on quality outcomes at the state level.
- Work to sustain the Medicaid and CHIP Payment and Access Commission (MACPAC) to advance policy analysis and health services research as they apply to CHIP.
7. Ensure adequate payment for practitioners who care for CHIP patients.
 - Require plans that contract with stand-alone CHIP programs to cover full costs of all new vaccines effective on the publication date of recommendations by the AAP or the Centers for Disease Control and Prevention in the *Morbidity and Mortality Weekly Report (MMWR)*. Coverage and payments must cover the costs of the vaccine adequately such that they include the total direct and indirect vaccine expense overhead as well as the related immunization administration service. Payment for the vaccine product should be at least 125% of the current Centers for Disease Control and Prevention vaccine price list. Payment for immunization administration must be at least 100% of the current Medicare Resource-Based Relative Value Scale (RBRVS) physician fee schedule.
 - To improve the adoption of effective medical home strategies by primary care pediatricians, require CHIP payers for

stand-alone programs to include payments for care coordination, telephone consultation, case management, hospital transition planning, and subspecialty care coordination.

- Create and maintain funding mechanisms to award achievement of recognized, evidence-based, outcome-driven quality-of-care standards for CHIP enrollees.
- Extend Medicaid payment parity permanently and extend parity to all billable services, including specialists and subspecialists.

CONCLUSIONS

Near-poor children in the United States have derived enormous benefits from

CHIP since its inception 16 years ago. The reauthorization of this landmark social insurance program in 2009 strengthened many of its most important elements and added innovative features that broadened its reach. With the passage of the ACA, the approach that the United States will adopt for this vulnerable segment of the pediatric population after 2015 is now subject to some uncertainty. Whether CHIP proves to have been an interim approach that is ultimately replaced by universal coverage through a combination of Medicaid, employer-sponsored health insurance, and insurance exchanges or by adoption of a single-payer system or whether CHIP endures in its current form even after full implementation of the ACA, it is vital for the health of near-

poor children that the principles of expanded access, affordable coverage, generous benefits, and quality monitoring be essential elements in the provision of health care services now and into the future.

abstract

FREE

Global developmental delay and intellectual disability are relatively common pediatric conditions. This report describes the recommended clinical genetics diagnostic approach. The report is based on a review of published reports, most consisting of medium to large case series of diagnostic tests used, and the proportion of those that led to a diagnosis in such patients. Chromosome microarray is designated as a first-line test and replaces the standard karyotype and fluorescent in situ hybridization subtelomere tests for the child with intellectual disability of unknown etiology. Fragile X testing remains an important first-line test. The importance of considering testing for inborn errors of metabolism in this population is supported by a recent systematic review of the literature and several case series recently published. The role of brain MRI remains important in certain patients. There is also a discussion of the emerging literature on the use of whole-exome sequencing as a diagnostic test in this population. Finally, the importance of intentional comanagement among families, the medical home, and the clinical genetics specialty clinic is discussed. *Pediatrics* 2014;134:e903–e918

The purpose of this clinical report of the American Academy of Pediatrics (AAP) is to describe an optimal medical genetics evaluation of the child with intellectual disability (ID) or global developmental delays (GDDs). The intention is to assist the medical home in preparing families properly for the medical genetics evaluation process. This report addresses the advances in diagnosis and treatment of children with intellectual disabilities since the publication of the original AAP clinical report in 2006¹ and provides current guidance for the medical genetics evaluation. One intention is to inform primary care providers in the setting of the medical home so that they and families are knowledgeable about the purpose and process of the genetics evaluation. This report will emphasize advances in genetic diagnosis while updating information regarding the appropriate evaluation for inborn errors of metabolism and the role of imaging in this context. The reader is referred to the 2006 clinical report for background information that remains relevant, including the roles of the medical home or pediatric primary care provider.

This clinical report will not address the importance of developmental screening in the medical home, nor will it address the diagnostic

evaluation of the child with an autism spectrum disorder who happens to have ID as a co-occurring disability. (For AAP guidance related to Autism Spectrum Disorders, see Johnson and Myers.²)

For both pediatric primary care providers and families, there are specific benefits to establishing an etiologic diagnosis (Table 1): clarification of etiology; provision of prognosis or expected clinical course; discussion of genetic mechanism(s) and recurrence risks; refined treatment options; the avoidance of unnecessary and redundant diagnostic tests; information regarding treatment, symptom management, or surveillance for known complications; provision of condition-specific family support; access to research treatment protocols; and the opportunity for comanagement of patients, as appropriate, in the context of a medical home to ensure the best health, social, and health care services satisfaction outcomes for the child and family. The presence of an accurate etiologic diagnosis along with a knowledgeable, experienced, expert clinician is one factor in improving the psychosocial outcomes for children and with

intellectual disabilities and their families.^{3–5} Although perhaps difficult to measure, this “healing touch” contributes to the general well-being of the family. “As physicians we have experience with other children who have the same disorder, access to management programs, knowledge of the prognosis, awareness of research on understanding the disease and many other elements that when shared with the parents will give them a feeling that some control is possible.”⁵

Makela et al⁶ studied, in depth, 20 families of children with ID with and without an etiologic diagnosis and found that these families had specific stated needs and feelings about what a genetic diagnosis offers:

1. Validation: a diagnosis established that the problem (ID) was credible, which empowered them to advocate for their child.
2. Information: a diagnosis was felt to help guide expectations and management immediately and provide hope for treatment or cure in future.
3. Procuring services: the diagnosis assisted families in obtaining desired services, particularly in schools.
4. Support: families expressed the need for emotional companionship that a specific diagnosis (or “similar challenges”) assisted in accessing.
5. Need to know: families widely differed in their “need to know” a specific diagnosis, ranging from strong to indifferent.
6. Prenatal testing: families varied in their emotions, thoughts, and actions regarding prenatal genetic diagnosis.

For some families in the Makela et al⁶ study, the clinical diagnosis of autism, for example, was sufficient and often more useful than “a rare but specific etiological diagnosis.” These authors report that “all of the families would

have preferred to have an [etiologic] diagnosis, if given the option,” particularly early in the course of the symptoms.

As was true of the 2006 clinical report, this clinical report will not address the etiologic evaluation of young children who are diagnosed with cerebral palsy, autism, or a single-domain developmental delay (gross motor delay or specific language impairment).¹ Some children will present both with GDD and clinical features of autism. In such cases, the judgment of the clinical geneticist will be important in determining the evaluation of the child depending on the primary neurodevelopmental diagnosis. It is recognized that the determination that an infant or young child has a cognitive disability can be a matter of clinical judgment, and it is important for the pediatrician and consulting clinical geneticist to discuss this before deciding on the best approach to the diagnostic evaluation.”¹

INTELLECTUAL DISABILITY

ID is a developmental disability presenting in infancy or the early childhood years, although in some cases, it cannot be diagnosed until the child is older than ~5 years of age, when standardized measures of developmental skills become more reliable and valid. The American Association on Intellectual and Developmental Disability defines ID by using measures of 3 domains: intelligence (IQ), adaptive behavior, and systems of supports afforded the individual.⁷ Thus, one cannot rely solely on the measure of IQ to define ID. More recently, the term ID has been suggested to replace “mental retardation.”^{7,8} For the purposes of this clinical report, the American Association on Intellectual and Developmental Disability definition is used: “Intellectual disability is a disability characterized by

TABLE 1 The Purposes of the Comprehensive Medical Genetics Evaluation of the Young Child With GDD or ID

1. Clarification of etiology
2. Provision of prognosis or expected clinical course
3. Discussion of genetic mechanism(s) and recurrence risks
4. Refined treatment options
5. Avoidance of unnecessary or redundant diagnostic tests
6. Information regarding treatment, symptom management, or surveillance for known complications
7. Provision of condition-specific family support
8. Access to research treatment protocols
9. Opportunity for comanagement of appropriate patients in the context of a medical home to ensure the best health, social, and health care services satisfaction outcomes for the child and family

significant limitations both in intellectual functioning and in adaptive behavior as expressed in conceptual, social and practical adaptive skills. The disability originates before age 18 years.”⁷ The prevalence of ID is estimated to be between 1% and 3%. Lifetime costs (direct and indirect) to support individuals with ID are large, estimated to be an average of approximately \$1 million per person.⁹

Global Developmental Delay

Identifying the type of developmental delay is an important preliminary step, because typing influences the path of investigation later undertaken. GDD is defined as a significant delay in 2 or more developmental domains, including gross or fine motor, speech/language, cognitive, social/personal, and activities of daily living and is thought to predict a future diagnosis of ID.¹⁰ Such delays require accurate documentation by using norm-referenced and age-appropriate standardized measures of development administered by experienced developmental specialists. The term GDD is reserved for younger children (ie, typically younger than 5 years), whereas the term ID is usually applied to older children for whom IQ testing is valid and reliable. Children with GDD are those who present with delays in the attainment of developmental milestones at the expected age; this implies deficits in learning and adaptation, which suggests that the delays are significant and predict later ID. However, delays in development, especially those that are mild, may be transient and lack predictive reliability for ID or other developmental disabilities. For the purposes of this report, children with delays in a single developmental domain (for example, isolated mild speech delay) should not be considered appropriate candidates for the comprehensive genetic evaluation process set forth here. The prevalence

of GDD is estimated to be 1% to 3%, similar to that of ID.

Diagnosis

Schaefer and Bodensteiner¹¹ wrote that a specific diagnosis is that which “can be translated into useful clinical information for the family, including providing information about prognosis, recurrence risks, and preferred modes of available therapy.” For example, agenesis of the corpus callosum is considered a sign and not a diagnosis, whereas the autosomal-recessive Acrocallosal syndrome (agenesis of the corpus callosum and polydactyly) is a clinical diagnosis. Van Karnebeek et al¹² defined etiologic diagnosis as “sufficient literature evidence...to make a causal relationship of the disorder with mental retardation likely, and if it met the Schaefer-Bodensteiner definition.” This clinical report will use this Van Karnebeek modification of the Schaefer–Bodensteiner definition and, thus, includes the etiology (genetic mutation or genomic abnormality) as an essential element to the definition of a diagnosis.

Recommendations are best when established from considerable empirical evidence on the quality, yield, and usefulness of the various diagnostic investigations appropriate to the clinical situation. The evidence for this clinical report is largely based on many small- or medium-size case series and on expert opinion. The report is based on a review of the literature by the authors.

Highlights in This Clinical Report

Significant changes in genetic diagnosis in the last several years have made the 2006 clinical report out-of-date. First, the chromosome microarray (CMA) is now considered a first-line clinical diagnostic test for children who present with GDD/ID of unknown cause. Second, this report

highlights a renewed emphasis on the identification of “treatable” causes of GDD/ID with the recommendation to consider screening for inborn errors of metabolism in all patients with unknown etiology for GDD/ID.¹³

Nevertheless, the approach to the patient remains familiar to pediatric primary care providers and includes the child’s medical history (including prenatal and birth histories); the family history, which includes construction and analysis of a pedigree of 3 generations or more; the physical and neurologic examinations emphasizing the examination for minor anomalies (the “dysmorphology examination”); and the examination for neurologic or behavioral signs that might suggest a specific recognizable syndrome or diagnosis. After the clinical genetic evaluation, judicious use of laboratory tests, imaging, and other consultations on the basis of best evidence are important in establishing the diagnosis and for care planning.

CHROMOSOME MICROARRAY

CMA now should be considered a first-tier diagnostic test in all children with GDD/ID for whom the causal diagnosis is not known. G-banded karyotyping historically has been the standard first-tier test for detection of genetic imbalance in patients with GDD/ID for more than 35 years. CMA is now the standard for diagnosis of patients with GDD/ID, as well as other conditions, such as autism spectrum disorders or multiple congenital anomalies.^{14–24} The G-banded karyotype allows a cytogeneticist to visualize and analyze chromosomes for chromosomal rearrangements, including chromosomal gains (duplications) and losses (deletions). CMA performs a similar function, but at a much “higher resolution,” for genomic imbalances, thus increasing the sensitivity substantially. In their recent review of the CMA literature,

Visser et al²⁵ report the diagnostic rate of CMA to be at least twice that of the standard karyotype. CMA, as used in this clinical report, encompasses all current types of array-based genomic copy number analyses, including array-based comparative genomic hybridization and single-nucleotide polymorphism arrays (see Miller et al¹⁵ for a review of array types). With these techniques, a patient's genome is examined for detection of gains or losses of genome material, including those too small to be detectable by standard G-banded chromosome studies.^{26,27} CMA replaces the standard karyotype ("chromosomes") and fluorescent in situ hybridization (FISH) testing for patients presenting with GDD/ID of unknown cause. The standard karyotype and certain FISH tests remain important to diagnostic testing but now only in limited clinical situations (see Manning and Hudgins¹⁴) in which a specific condition is suspected (eg, Down syndrome or Williams syndrome). The discussion of CMA does not include whole-genome sequencing, exome sequencing, or "next-generation" genome sequencing; these are discussed in the "emerging technologies" section of this report.

Twenty-eight case series have been published addressing the rate of diagnosis by CMA of patients presenting with GDD/ID.²⁸ The studies vary by subject criteria and type of microarray technique and reflect rapid changes in technology over recent years. Nevertheless, the diagnostic yield for all current CMA is estimated at 12% for patients with GDD/ID.^{14–29} CMA is the single most efficient diagnostic test, after the history and examination by a specialist in GDD/ID.

CMA techniques or "platforms" vary. Generally, CMA compares DNA content from 2 differentially labeled genomes: the patient and a control. In the early techniques, 2 genomes were cohybridized, typically onto a glass microscope

slide on which cloned or synthesized control DNA fragments had been immobilized. Arrays have been built with a variety of DNA substrates that may include oligonucleotides, complementary DNAs, or bacterial artificial chromosomes. The arrays might be whole-genome arrays, which are designed to cover the entire genome, or targeted arrays, which target known pathologic loci, the telomeres, and pericentromeric regions. Some laboratories offer chromosome-specific arrays (eg, for nonsyndromic X-linked ID [XLID]).³⁰ The primary advantage of CMA over the standard karyotype or later FISH techniques is the ability of CMA to detect DNA copy changes simultaneously at multiple loci in a genome in one "experiment" or test. The copy number change (or copy number variant [CNV]) may include deletions, duplications, or amplifications at any locus, as long as that region is represented on the array. CMA, independent of whether it is "whole genome" or "targeted" and what type of DNA substrate (single-nucleotide polymorphisms,³¹ oligonucleotides, complementary DNAs, or bacterial artificial chromosomes),³² identifies deletions and/or duplications of chromosome material with a high degree of sensitivity in a more efficient manner than FISH techniques. Two main factors define the resolution of CMA: (1) the size of the nucleic acid targets; and (2) the density of coverage over the genome. The smaller the size of the nucleic acid targets and the more contiguous the targets on the native chromosome are, the higher the resolution is. As with the standard karyotype, one result of the CMA test can be "of uncertain significance," (ie, expert interpretation is required, because some deletions or duplications may not be clearly pathogenic or benign). Miller et al¹⁵ describe an effort to develop an international consortium of laboratories to address questions surrounding array-based testing interpretation. This

International Standard Cytogenomic Array Consortium¹⁵ (www.iscaconsortium.org) is investigating the feasibility of establishing a standardized, universal system of reporting and cataloging CMA results, both pathologic and benign, to provide the physician with the most accurate and up-to-date information.

It is important for the primary care pediatrician to work closely with the clinical geneticist and the diagnostic laboratory when interpreting CMA test results, particularly when "variants of unknown significance" are identified. In general, CNVs are assigned the following interpretations: (1) pathogenic (ie, abnormal, well-established syndromes, *de novo* variants, and large changes); (2) variants of unknown significance; and (3) likely benign.¹⁵ These interpretations are not essentially different than those seen in the standard G-banded karyotype. It is important to note that not all commercial health plans in the United States include this testing as a covered benefit when ordered by the primary care pediatrician; others do not cover it even when ordered by the medical geneticist. Typically, the medical genetics team has knowledge and experience in matters of payment for testing.

The literature does not stratify the diagnostic rates of CMA by severity of disability. In addition, there is substantial literature supporting the multiple factors (eg, social, environmental, economic, genetic) that contribute to mild disability.³³ Consequently, it remains within the judgment of the medical geneticist as to whether it is warranted to test the patient with mild (and familial) ID for pathogenic CNVs. In their review, Visser et al²⁵ reported on several recurrent deletion or duplication syndromes with mild disability and commented on the variable penetrance of the more common CNV conditions, such as 1q21.1

microdeletion, 1q21.1 microduplication, 3q29 microduplication, and 12q14 microdeletion. Some of these are also inherited. Consequently, among families with more than one member with disability, it remains challenging for the medical geneticist to know for which patient with GDD/ID CMA testing is not warranted.

Recent efforts to evaluate reporting of CNVs among clinical laboratories indicate variability of interpretation because of platform variability in sensitivity.^{34,35} Thus, the interpretation of CMA test abnormal results and variants of unknown significance, and the subsequent counseling of families should be performed in all cases by a medical geneticist and certified genetic counselor in collaboration with the reference laboratory and platform used. Test variability is resolving as a result of international collaborations.³⁶ With large data sets, the functional impact (or lack thereof) of very rare CNVs is better understood. Still, there will continue to be rare or unique CNVs for which interpretation remain ambiguous. The medical geneticist is best equipped to interpret such information to families and the medical home.

SCREENING FOR INBORN ERRORS OF METABOLISM

Since the 2006 AAP clinical report, several additional reports have been published regarding metabolic testing for a cause of ID.^{13,37–40} The percentage of patients with identifiable metabolic disorders as cause of the ID ranges from 1% to 5% in these reports, a range similar to those studies included in the 2006 clinical report. Likewise, these newer published case series varied by site, age range of patients, time frame, study protocol, and results. However, they do bring renewed focus to treatable metabolic disorders.¹³ Furthermore, some of the disorders identified

are not included currently in any newborn screening blood spot panels. Although the prevalence of inherited metabolic conditions is relatively low (0% to 5% in these studies), the potential for improved outcomes after diagnosis and treatment is high.⁴¹

In 2005, Van Karnebeek et al⁴⁰ reported on a comprehensive genetic diagnostic evaluation of 281 consecutive patients referred to an academic center in the Netherlands. All patients were subjected to a protocol for evaluation and studies were performed for all patients with an initially unrecognized cause of mental retardation and included urinary screen for amino acids, organic acids, oligosaccharides, acid mucopolysaccharides, and uric acid; plasma concentrations of total cholesterol and diene sterols of 7- and 8-dehydrocholesterol to identify defects in the distal cholesterol pathway; and a serum test to screen for congenital disorders of glycosylation (test names such as “carbohydrate-deficient transferrin”). In individual patients, other searches were performed as deemed necessary depending on results of earlier studies. This approach identified 7 (4.6%) subjects with “certain or probable” metabolic disorders among those who completed the metabolic screening ($n = 216$). None of the 176 screening tests for plasma amino acids and urine organic acids was abnormal. Four children (1.4%) with congenital disorders of glycosylation were identified by serum sialotransferrins, 2 children had abnormal serum cholesterol and 7-dehydrocholesterol concentrations suggestive of Smith-Lemli-Opitz syndrome, 2 had evidence of a mitochondrial disorder, 1 had evidence of a peroxisomal disorder, and 1 had abnormal cerebrospinal fluid biogenic amine concentrations. These authors concluded that “screening for glycosylation defects proved useful,

whereas the yield of organic acid and amino acid screening was negligible.”

In a similar study from the Netherlands done more recently, Engbers et al³⁹ reported on metabolic testing that was performed in 433 children whose GDD/ID remained unexplained after genetic/metabolic testing, which included a standard karyotype; urine screen for amino acids, organic acids, mucopolysaccharides, oligosaccharides, uric acid, sialic acid, purines, and pyrimidines; and plasma for amino acids, acylcarnitines, and sialotransferrins. Screenings were repeated, and additional testing, including cerebrospinal fluid studies, was guided by clinical suspicion. Metabolic disorders were identified and confirmed in 12 of these patients (2.7%), including 3 with mitochondrial disorders; 2 with creatine transporter disorders; 2 with short-chain acyl-coenzyme A dehydrogenase deficiency; and 1 each with Sanfilippo IIIa, a peroxisomal disorder; a congenital disorder of glycosylation; 5-methyltetrahydrofolate reductase deficiency; and deficiency of the GLUT1 glucose transporter.

Other studies have focused on the prevalence of disorders of creatine synthesis and transport. Lion-François et al³⁷ reported on 188 children referred over a period of 18 months with “unexplained mild to severe mental retardation, normal karyotype, and absence of fragile X syndrome” who were prospectively screened for congenital creatine deficiency syndromes. Children were from diverse ethnic backgrounds. Children with “polymalformative syndromes” were excluded. There were 114 boys (61%) and 74 girls (39%) studied. Creatine metabolism was evaluated by using creatine/creatinine and guanidinoacetate (GAA)-to-creatinine ratios on a spot urine screen. Diagnosis was further confirmed by using brain proton magnetic resonance spectroscopy and mutation screening by DNA sequence analysis in

either the *SLC6A8* (creatine transporter defect) or the *GAMT* genes. This resulted in a diagnosis in 5 boys (2.7% of all; 4.4% of boys). No affected girls were identified among the 74 studied. All 5 boys also were late to walk, and 3 had “autistic features.” The authors concluded that all patients with undiagnosed ID have urine screened for creatine-to-creatinine ratio and GAA-to-creatine ratio. Similarly, Caldeira Araujo et al³⁸ studied 180 adults with ID institutionalized in Portugal, screening them for congenital creatine deficiency syndromes. Their protocol involved screening all subjects for urine and plasma uric acid and creatinine. Patients with an increased urinary uric acid-to-creatinine ratio and/or decreased creatinine were subjected to the analysis of GAA. *GAMT* activity was measured in lymphocytes and followed by *GAMT* gene analysis. This resulted in identifying 5 individuals (2.8%) from 2 families with *GAMT* deficiency. A larger but less selective study of 1600 unrelated male and female children with GDD/ID and/or autism found that 34 (2.1%) had abnormal urine creatine-to-creatinine ratios, although only 10 (0.6%) had abnormal repeat tests and only 3 (0.2%) were found to have an *SLC6A8* mutation.⁴² Clark et al⁴³ identified *SLC6A8* mutations in 0.5% of 478 unrelated boys with unexplained GDD/ID.

Recently, van Karnebeek and Stockler reported^{13,42} on a systematic literature review of metabolic disorders “presenting with intellectual disability as a major feature.” The authors identified 81 treatable genetic metabolic disorders presenting with ID as a major feature. Of these disorders, 50 conditions (62%) were identified by routinely available tests (Tables 2 and 3). Therapeutic modalities with proven effect included diet, cofactor/vitamin supplements, substrate inhibition, en-

zyme replacement, and hematopoietic stem cell transplant. The effect on outcome (IQ, developmental performance, behavior, epilepsy, and neuroimaging) varied from improvement to halting or slowing neurocognitive regression. The authors emphasized the approach as one that potentially has significant impact on patient outcomes: “This approach revisits current paradigms for the diagnostic evaluation of ID. It implies treatability as the premise in the etiologic work-up and applies evidence-based medicine to rare diseases.” Van Karnebeek and Stockler^{13,42} reported on 130 patients with ID who were “tested” per this metabolic protocol; of these, 6 (4.6%) had confirmed treatable inborn errors of metabolism and another 5 (3.8%) had “probable” treatable inborn error of metabolism.

This literature supports the need to consider screening children presenting with GDD/ID for treatable metabolic conditions. Many metabolic screening tests are readily available to the medical home and/or local hospital laboratory service. Furthermore, the costs for these metabolic screening tests are relatively low.

GENETIC TESTING FOR MENDELIAN DISORDERS

For patients in whom a diagnosis is suspected, diagnostic molecular genetic testing is required to confirm the diagnosis so that proper health care is

implemented and so that reliable genetic counseling can be provided. For patients with a clinical diagnosis of a Mendelian disorder that is certain, molecular genetic diagnostic testing usually is not required to establish the diagnosis but may be useful for health care planning. However, for carrier testing or for genetic counseling of family members, it is often essential to know the specific gene mutation in the proband.

For patients with GDD/ID for whom the diagnosis is not known, molecular genetic diagnostic testing is necessary, under certain circumstances, which is discussed in the next section.

MALE GENDER

There is an approximate 40% excess of boys in all studies of prevalence and incidence of ID.^{44,45} Part of this distortion of the gender ratio is attributable to X-linked genetic disorders.⁴⁶ Consequently, genetic testing for X-linked genes in boys with GDD/ID is often warranted, particularly in patients whose pedigree is suggestive of an X-linked condition. In addition, for several reasons, research in X-linked genes that cause ID is advanced over autosomal genes,^{46,47} thus accelerating the clinical capacity to diagnose XLID over autosomal forms.

Most common of these is fragile X syndrome, although the prevalence of all other X-linked genes involved in ID

^a Late-onset form of condition listed; some conditions are identified by more than 1 metabolic test.

far exceeds that of fragile X syndrome alone.⁴⁶ Fragile X testing should be performed in all boys and girls with GDD/ID of unknown cause. Of boys with GDD/ID of uncertain cause, 2% to 3% will have fragile X syndrome (full mutation of *FMR1*, >200 CGG repeats), as will 1% to 2% of girls (full mutation).⁴⁸

GENETIC TESTING FOR NONSPECIFIC XLID

Stevenson and Schwartz⁴⁹ suggest 2 clinical categories for those with XLID: syndromal and nonsyndromal. Syndromal refers to patients in whom physical or neurologic signs suggest a specific diagnosis; nonsyndromal refers to those with no signs or symptoms to guide the diagnostic process. Using this classification has practical applicability, because the pediatric primary care provider can establish a specific XLID syndrome on the basis of clinical findings. In contrast, nonsyndromal conditions can only be distinguished on the basis of the knowledge of their causative gene.⁵⁰ In excess of 215 XLID conditions have been recorded, and >90 XLID genes have been identified.^{46,50}

To address male patients with GDD/ID and X-linked inheritance, there are molecular genetic diagnostic “panels” of X-linked genes available clinically. These panels examine many genes in 1 “test sample.” The problem for the clinical evaluation is in which patient to use which test panel, because there is no literature on head-to-head performance of test panels, and the test panels differ somewhat by genes included, test methods used, and the rate of a true pathogenic genetic diagnosis. Nevertheless, the imperative for the diagnostic evaluation remains the same for families and physicians, and there is a place for such testing in the clinical evaluation of children with GDD/ID. For patients with an

X-linked pedigree, genetic testing using one of the panels is clinically indicated. The clinical geneticist is best suited to guide this genetic testing of patients with possible XLID. For patients with “syndromal” XLID (eg, Coffin-Lowry syndrome), a single gene test rather than a gene panel is indicated. Whereas those patients with “nonsyndromal” presentation might best be assessed by using a multigene panel comprising many of the more common nonsyndromal XLID genes. The expected rate of the diagnosis may be high. Stevenson and Schwartz⁴⁶ reported, for example, on 113 cases of nonspecific ID testing using a 9-gene panel of whom 9 (14.2%) had pathogenic mutations identified. de Brouwer et al⁵¹ reported on 600 families with multiple boys with GDD/ID and normal karyotype and *FMR1* testing. Among those families with “an obligate female carrier” (defined by pedigree analysis and linkage studies), a specific gene mutation was identified in 42%. In addition, in those families with more than 2 boys with ID and no obligate female carrier or without linkage to the X chromosome, 17% of the ID cases could be explained by X-linked gene mutations. This very large study suggested that testing of individual boys for X-linked gene mutations is warranted.

Recently, clinical laboratories have begun offering “high-density” X-CMAs to assess for pathogenic CNVs (see previous discussion regarding microarrays) specifically for patients with XLID. Wibley et al⁵⁰ (2010) reported on CNVs in 251 families with evidence of XLID who were investigated by array comparative genomic hybridization on a high-density oligonucleotide X-chromosome array platform. They identified pathogenic CNVs in 10% of families. The high-density arrays for XLID are appropriate in those patients with syndromal or nonsyndromal XLID.

The expected diagnostic rate remains uncertain, although many pathogenic segmental duplications are reported (for a catalog of X-linked mutations and CNVs, see <http://www.ggc.org/research/molecular-studies/xlid.html>).

Whole exome sequencing and whole-genome sequencing are emerging testing technologies for patients with nonspecific XLID. Recently, Tarpey et al⁵² have reported the results of the large-scale systematic resequencing of the coding X chromosome to identify novel genes underlying XLID. Gene coding sequences of 718 X-chromosome genes were screened via Sanger sequencing technology in probands from 208 families with probable XLID. This resequencing screen contributed to the identification of 9 novel XLID-associated genes but identified pathogenic sequence variants in only 35 of 208 (17%) of the cohort families. This figure likely underestimates the general contribution of sequence variants to XLID given the subjects were selected from a pool that had had previous clinical and molecular genetic screening.³⁰

BOYS WITH SUSPECTED OR KNOWN XLID

Table 4 lists some common XLID conditions. In cases in which the diagnosis is not certain, molecular genetic testing of patients for the specific gene is indicated, even if the pedigree does not indicate other affected boys (ie, cannot confirm X-linked inheritance).⁴⁶

FEMALE GENDER AND MECP2 TESTING

Rett syndrome is an X-linked condition that affects girls and results from *MECP2* gene mutations primarily (at least 1 other gene has been determined causal in some patients with typical and atypical Rett syndrome: *CDKL5*). Girls with mutations in the

MECP2 gene do not always present clinically with classic Rett syndrome. Several large case series have examined the rate of pathogenic *MECP2* mutations in girls and boys with ID. The proportion of *MECP2* mutations in these series ranged from 0% to 4.4% with the average of 1.5% among girls with moderate to severe ID.^{53–62} *MECP2* mutations in boys present with severe neonatal encephalopathy and not with GDD/ID.

ADVANCES IN DIAGNOSTIC IMAGING

Currently, the literature does not indicate consensus on the role that neuroimaging, either by computed tomography (CT) or MRI, can play in the evaluation of children with GDD/ID. Current recommendations range from performing brain imaging on all patients with GDD/ID,⁶³ to performing it only on those with indications on clinical examination,¹² to being considered as a second-line investigation to be undertaken when features in addition to GDD are detected either on history or physical examination. The finding of a brain abnormality or anomaly on neuroimaging may lead to the recognition of a specific cause of an individual child's developmental delay/ID in the same way that a dysmorphologic examination might lead to the inference of a particular clinical diagnosis. However, like other major or minor anomalies noted on physical examination, abnormalities on neuroimaging typically are not sufficient for determining the cause of the developmental delay/ID; the underlying precise, and presumably frequently genetic in origin, cause of the brain anomaly is often left unknown. Thus, although a central nervous system (CNS) anomaly (often also called a "CNS dysgenesis") is a useful finding and indeed may be considered, according to the definition of Schaefer and Bodensteiner,¹¹ a useful "diagnosis."

However, it is frequently not an etiologic or syndromic diagnosis. This distinction is not always made in the literature on the utility of neuroimaging in the evaluation of children with developmental delay/ID. The lack of a consistent use of this distinction has led to confusion regarding this particular issue.

Early studies on the use of CT in the evaluation of children with idiopathic ID⁶⁴ indicated a low diagnostic yield for the nonspecific finding of "cerebral atrophy," which did not contribute to clarifying the precise cause of the ID.⁶⁵ Later studies that used MRI to detect CNS abnormalities suggested that MRI was more sensitive than CT, with an increased diagnostic yield.^{10,66} The rate of abnormalities actually detected on imaging varies widely in the literature as a result of many factors, such as subject selection and the method of imaging used (ie, CT or MRI). Schaefer and Bodensteiner,⁶³ in their literature review, found reported ranges of abnormalities from 9% to 80% of those patients studied. Shevell et al¹⁰ reported a similar range of finding in their review. For example, in 3 studies totaling 329 children with developmental delay in which CT was used in almost all patients and MRI was used in but a small sample, a specific cause was determined in 31.4%,⁶⁷ 27%,⁶⁸ and 30%⁶⁹ of the children. In their systematic review of the literature, van Karnebeek et al¹² reported on 9 studies that used MRI in children with ID. The mean rate of abnormalities found was 30%, with a range of 6.2% to 48.7%. These investigators noted that more abnormalities were found in children with moderate to profound ID versus those with borderline to mild ID (mean yield of 30% and 21.2%, respectively). These authors also noted that none of the studies reported on the value of the absence of any neurologic abnormality for a diagnostic workup and

concluded that "the value for finding abnormalities or the absence of abnormalities must be higher" than the 30% mean rate implied.

If neuroimaging is performed in only selected cases, such as children with an abnormal head circumference or an abnormal focal neurologic finding, the rate of abnormalities detected is increased further than when used on a screening basis in children with a normal neurologic examination except for the documentation of developmental delay. Shevell et al⁶⁸ reported that the percentage of abnormalities were 13.9% if neuroimaging was performed on a "screening basis" but increased to 41.2% if performed on "an indicated basis." Griffiths et al⁷⁰ highlighted that the overall risk of having a specific structural abnormality found on MRI scanning was 28% if neurologic symptoms and signs other than developmental delay were present, but if the developmental delay was isolated, the yield was reduced to 7.5%. In a series of 109 children, Verbruggen et al⁷¹ reported an etiologic yield on MRI of 9%. They noted that all of these children had neurologic signs or an abnormal head circumference. In their practice parameter, the American Academy of Neurology and the Child Neurology Society¹⁰ discussed other studies on smaller numbers of patients who showed similar results, which led to their recommendation that "neuroimaging is a recommended part of the diagnostic evaluation," particularly should there be abnormal findings on examination (ie, microcephaly, macrocephaly, focal motor findings, pyramidal signs, extrapyramidal signs) and that MRI is preferable to CT. However, the authors of the American College of Medical Genetics Consensus Conference Report¹⁰ stated that neuroimaging by CT or MRI in normocephalic patients without focal neurologic signs should not be considered a "standard of

TABLE 4 Common Recognizable XLID Syndromes

Syndrome	Common Manifestations	Gene, Location
Aarskog syndrome	Short stature, hypertelorism, downslanting palpebral fissures, joint hyperextensibility, shawl scrotum	<i>FGD1</i> , Xp11.21
Adrenoleukodystrophy	Variable and progressive vision and hearing loss, spasticity, neurological deterioration associated with demyelination of the central nervous system and adrenal insufficiency	<i>ABCD1</i> , Xq28
Aicardi syndrome	Agenesis of the corpus callosum, lacunar chorioretinopathy, costovertebral anomalies, seizures in females	_____, Xp22
Allan–Herndon syndrome	Generalized muscle hypoplasia, childhood hypotonia, ataxia, athetosis, dysarthria, progressing to spastic paraplegia	<i>MCT8</i> (SLC16A2), Xq13
ARX-related syndromes (includes Partington, Proud, West, XLAG syndromes and nonsyndromal XLMR)	Partington: dysarthria, dystonia, hyperreflexia, seizures. West: infantile spasms, hypsarrhythmia. Proud: microcephaly, ACC, spasticity, seizures, ataxia, genital anomalies. XLAG: lissencephaly, seizures, genital anomalies	<i>ARX</i> , Xp22.3
ATRX syndrome (includes ARTX, Chudley–Lowry, Carpenter–Waziri, Holmes–Gang, and Martinez spastic paraplegia syndromes and nonsyndromal XLMR)	Short stature, microcephaly, hypotonic facies with hypertelorism, small nose, open mouth and prominent lips, brachydactyly, genital anomalies, hypotonia, in some cases hemoglobin H inclusions in erythrocytes	<i>XNP</i> , (XH2) Xq13.3
Christianson syndrome	Short stature, microcephaly, long narrow face, large ears, long straight nose, prominent mandible, general asthenia, narrow chest, long thin digits, adducted thumbs, contractures, seizures, autistic features, truncal ataxia, ophthalmoplegia, mutism, incontinence, hypoplasia of the cerebellum, and brain stem	<i>SLC9A6</i> , Xq26
Coffin–Lowry syndrome	Short stature, distinctive facies, large soft hands, hypotonia, joint hyperextensibility, skeletal changes	<i>RSK2</i> , Xp22
Creatine transporter deficiency	Nondysmorphic, autistic, possibly progressive	<i>SLC6A8</i> , Xq28
Duchenne muscular dystrophy	Pseudohypertrophic muscular dystrophy	<i>DMD</i> , Xp21.3
Fragile X syndrome	Prominent forehead, long face, recessed midface, large ears, prominent mandible, macroorchidism	<i>FMR1</i> , Xq27.3
Hunter syndrome	Progressive coarsening of face, thick skin, cardiac valve disease, joint stiffening, dysostosis multiplex	<i>IDS</i> , Xq28
Incontinentia pigmenti	Sequence of cutaneous blistering, verrucous thickening, and irregular pigmentation. May have associated CNS, ocular abnormalities	<i>NEMO</i> (IKB6KG), Xq28
Lesch–Nyhan syndrome	Choreoathetosis, spasticity, seizures, self-mutilation, uric acid urinary stones	<i>HPRT</i> , Xq26
Lowe syndrome	Short stature, cataracts, hypotonia, renal tubular dysfunction	<i>OCRL</i> , Xq26.1
MECP2 duplication syndrome	Hypotonia, progressing to spastic paraplegia, recurrent infections	<i>MECP2</i> , Xq28
Menkes syndrome	Growth deficiency, full cheeks, sparse kinky hair, metaphyseal changes, limited spontaneous movement, hypertonicity, seizures, hypothermia, lethargy, arterial tortuosity, death in early childhood	<i>ATP7A</i> , Xp13.3
Pelizaeus–Merzbacher disease	Nystagmus, truncal hypotonia, progressive spastic paraplegia, ataxia, dystonia	<i>PLP</i> , Xq21.1
Renpenning syndrome (includes Sutherland–Haan, cerebropalatocardiac, Golabi–Ito–Hall, Porteous syndrome)	Short stature, microcephaly, small testes. May have ocular or genital abnormalities	<i>PQBPI</i> , Xp11.3
Rett syndrome	XLMR in girls, cessation and regression of development in early childhood, truncal ataxia, autistic features, acquired microcephaly	<i>MECP2</i> , Xq28
X-linked hydrocephaly-MASA spectrum	Hydrocephalus, adducted thumbs, spastic paraplegia	<i>L1CAM</i> , Xq28

Reproduced with permission from Stevenson and Schwartz.⁴⁶

practice” or mandatory and believed that decisions regarding “cranial imaging will need to follow (not precede) a thorough assessment of the patient and the clinical presentation.” In contrast, van Karnebeek et al¹² found that

MRI alone leads to an etiologic diagnosis in a much lower percentage of patients studied. They cited Kjos et al,⁷² who reported diagnoses in 3.9% of patients who had no known cause for their ID and who did not manifest either

a progressive or degenerative course in terms of their neurologic symptomatology. Bouhadiba et al⁷³ reported diagnoses in 0.9% of patients with neurologic symptoms, and in 4 additional studies, no etiologic or syndromic

diagnosis on the basis of neuroimaging alone was found.^{65,69,74,75} The authors of 3 studies reported the results on unselected patients; Majnemer and Shevell⁶⁷ reported a diagnosis by this typed unselected investigation in 0.2%, Stromme⁷⁶ reported a diagnosis in 1.4% of patients, and van Karnebeek et al⁴⁰ reported a diagnosis in 2.2% of patients.

Although a considerable evolution has occurred over the past 2 decades in neuroimaging techniques and modalities, for the most part with the exception of proton magnetic resonance spectroscopy, this has not been applied or reported in the clinical situation of developmental delay/ID in childhood. Proton resonance spectroscopy provides a noninvasive mechanism of measuring brain metabolites, such as lactate, using technical modifications to MRI. Martin et al⁷⁷ did not detect any differences in brain metabolite concentrations among stratifications of GDD/ID into mild, moderate, and severe levels. Furthermore, they did not detect any significant differences in brain metabolite concentration between children with GDD/ID and age-matched typically developing control children. Thus, these authors concluded that proton resonance spectroscopy “has little information concerning cause of unexplained DD.” Similarly, the studies by Martin et al⁷⁷ and Verbruggen et al⁷¹ did not reveal that proton magnetic resonance spectroscopy was particularly useful in the determination of an underlying etiologic diagnosis in children with unexplained developmental delay/ID.

All of these findings suggest that abnormal findings on MRI are seen in ~30% of children with developmental delay/ID. However, only in a fraction of these children does MRI lead to an etiologic or syndromic diagnosis. The precise value of a negative MRI result in leading to a diagnosis has not yet

been studied in detail. In addition, MRI in the young child with developmental delay/ID invariably requires sedation or, in some cases, anesthesia to immobilize the child to accomplish the imaging study. This need, however, is decreasing with faster acquisition times provided by more modern imaging technology. Although the risk of sedation or anesthesia is small, it still merits consideration within the decision calculus for practitioners and the child's family.^{63,78,79} Thus, although MRI is often useful in the evaluation of the child with developmental delay/ID, at present, it cannot be definitively recommended as a mandatory study, and it certainly has higher diagnostic yields when concurrent neurologic indications exist derived from a careful physical examination of the child (ie, microcephaly, macrocephaly, seizures, or focal motor findings).

RECOMMENDED APPROACH

The following is the recommended medical genetic diagnostic evaluation flow process for a new patient with GDD/ID. All patients with ID, irrespective of degree of disability, merit a comprehensive medical evaluation coordinated by the medical home in conjunction with the medical genetics specialist. What follows is the clinical genetics evaluation (Fig 1):

1. Complete medical history; 3-generation family history; and physical, dysmorphicologic, and neurologic examinations.
2. If the specific diagnosis is certain, inform the family and the medical home, providing informational resources for both; set in place an explicit shared health care plan⁸⁰ with the medical home and family, including role definitions; provide sources of information and support to the family; provide genetic counseling services by a certified genetic counselor; and discuss

treatment and prognosis. Confirm the clinical diagnosis with the appropriate genetic testing, as warranted by clinical circumstances.

3. If a specific diagnosis is suspected, arrange for the appropriate diagnostic studies to confirm including single-gene tests or chromosomal microarray test.
4. If diagnosis is unknown and no clinical diagnosis is strongly suspected, begin the stepwise evaluation process:
 - a. Chromosomal microarray should be performed in all.
 - b. Specific metabolic testing should be considered and should include serum total homocysteine, acyl-carnitine profile, amino acids; and urine organic acids, glycosaminoglycans, oligosaccharides, purines, pyrimidines, GAA/creatine metabolites.
 - c. Fragile X genetic testing should be performed in all.
5. If no diagnosis is established:
 - a. Male gender and family history suggestive X-linkage, complete XLID panel that contains genes causal of nonsyndromic XLID and complete high-density X-CMA. Consider X-inactivation skewing in the mother of the proband.
 - b. Female gender: complete *MECP2* deletion, duplication, and sequencing study.
6. If microcephaly, macrocephaly, or abnormal findings on neurologic examination (focal motor findings, pyramidal signs, extrapyramidal signs, intractable epilepsy, or focal seizures), perform brain MRI.
7. If brain MRI findings are negative or normal, review status of diagnostic evaluation with family and medical home.
8. Consider referrals to other specialists, signs of inborn errors of metabolism

**FIGURE 1**

Diagnostic process and care planning. Metabolic test 1: blood homocysteine, acylcarnitine profile, amino acids; and, urine organic acids, glycosaminoglycans, oligosaccharides, purines, pyrimidines, GAA/creatine metabolites. Metabolic test 2 based on clinical signs and symptoms. FH, family history; MH, medical history; NE, neurologic examination; PE, physical and dysmorphology examination.

for which screening has not yet been performed, etc.

9. If no further studies appear warranted, develop a plan with the family and medical home for needed services for child and family; also develop a plan for diagnostic reevaluation.

THE SHARED EVALUATION AND CARE PLAN FOR LIMITED ACCESS

Health care systems, processes, and outcomes vary geographically, and not all of what is recommended in this clinical report is easily accessible in all regions of the United States.^{21,81–84} Consequently, local factors affect the

process of evaluation and care. These arrangements are largely by local custom or design. In some areas, there may be quick access and intimate coordination between the medical home and medical genetics specialist, but in other regions, access may be constrained by distance or by decreased capacity, making for long wait times for appointments. Some general pediatricians have the ability to interpret the results of genetic testing that they may order. In addition, children with GDD or ID are often referred by pediatricians to developmental pediatricians, child neurologists, or other subspecialists. It is appropriate for some elements of the medical genetic evaluation to be performed by physicians other than medical geneticists if they have the ability to interpret the test results and provide appropriate counseling to the families. In such circumstances, the diagnostic evaluation process can be designed to address local particularities. The medical home is responsible for referrals of the family and child to the appropriate special education or early developmental services professional for individualized services. In addition, the medical home can begin the process of the diagnostic evaluation if access is a problem and in coordination with colleagues in medical genetics.^{80,85} What follows is a suggested process for the evaluation by the medical home and the medical genetics specialist and only applies where access is a problem; any such process is better established with local particularities in mind:

Medical home completes the medical evaluation, determines that GDD/ID is present, counsels family, refers to educational services, completes a 3-generation family history, and completes the physical examination and addresses the following questions:

1. Does the child have abnormalities on the dysmorphologic examination?

- a. If no or uncertain, obtain microarray, perform fragile X testing, and consider the metabolic testing listed previously. Confirm that newborn screening was completed and reported negative. Refer to medical genetics while testing is pending.
 - b. If yes, send case summary and clinical photo to medical genetics center for review for syndrome identification. If diagnosis is suspected, arrange for expedited medical genetics referral and hold all testing listed above. Medical geneticist to arrange visit with genetic counselor for testing for suspected condition.
2. Does the child have microcephaly, macrocephaly, or abnormal neurologic examination (listed above)? If "yes," measure parental head circumferences and review the family history for affected and unaffected members. If normal head circumferences in both parents and negative family history, obtain brain MRI and refer to medical genetics.
 3. Does child also have features of autism, cerebral palsy, epilepsy, or sensory disorders (deafness, blindness)? This protocol does not address these patients; manage and refer as per local circumstances.
 4. As above are arranged and completed and negative, refer to medical genetics and hold on additional diagnostic testing until consultation completed. Continue with current medical home family support services and health care.
 5. Should a diagnosis be established, the medical home, medical geneticist, and family might then agree to a care plan with explicit roles and responsibilities of all.
 6. Should a diagnosis not be established by medical genetics consultation, the medical home, family, and

medical geneticist can then agree on the frequency and timing of diagnostic reevaluation while providing the family and child services needed.

EMERGING TECHNOLOGIES

Several research reports have cited whole-exome sequencing and whole-genome sequencing in patients with known clinical syndromes for whom the causative gene was unknown. These research reports identified the causative genes in patients with rare syndromes (eg, Miller syndrome,⁸⁶ Charcot-Marie-Tooth disease,⁸⁷ and a child with severe inflammatory bowel disease⁸⁸). Applying similar whole-genome sequencing of a family of 4 with 1 affected individual, Roach et al⁸⁶ identified the genes for Miller syndrome and primary ciliary dyskinesia. The ability to do whole-genome sequencing and interpretation at an acceptable price is on the horizon.^{87,89} The use of exome or whole-genome sequencing challenges the field of medical genetics in ways not yet fully understood. When a child presents with ID and whole-genome sequencing is applied, one will identify mutations that are unrelated to the question being addressed, in this case "What is the cause of the child's intellectual disability?" One assumes that this will include mutations that families do not want to have (eg, adult-onset disorders for which no treatment now exists). This is a sea change for the field of medical genetics, and the implications of this new technology have not been fully explored. In addition, ethical issues regarding validity of new tests, uncertainty, and use of resources will need to be addressed as these technologies become available for clinical use.^{90,91}

CONCLUSIONS

The medical genetic diagnostic evaluation of the child with GDD/ID is best accomplished in collaboration with the medical home and family by using this

clinical report to guide the process. The manner in which the elements of this clinical protocol are applied is subject to local circumstances, as well as the decision-making by the involved pediatric primary care provider and family. The goals and the process of the diagnostic evaluation are unchanged: to improve the health and well-being of those with GDD/ID. It is important to emphasize the new role of the genomic microarray as a first-line test, as well as the renewal of efforts to identify the child with an inborn error of metabolism. The future use of whole-genome sequencing offers promise and challenges needing to be addressed before regular implementation in the clinic.

Contraception for Adolescents

.....

- *Policy Statement*

POLICY STATEMENT

Contraception for Adolescents

abstract

FREE

Contraception is a pillar in reducing adolescent pregnancy rates. The American Academy of Pediatrics recommends that pediatricians develop a working knowledge of contraception to help adolescents reduce risks of and negative health consequences related to unintended pregnancy. Over the past 10 years, a number of new contraceptive methods have become available to adolescents, newer guidance has been issued on existing contraceptive methods, and the evidence base for contraception for special populations (adolescents who have disabilities, are obese, are recipients of solid organ transplants, or are HIV infected) has expanded. The Academy has addressed contraception since 1980, and this policy statement updates the 2007 statement on contraception and adolescents. It provides the pediatrician with a description and rationale for best practices in counseling and prescribing contraception for adolescents. It is supported by an accompanying technical report. *Pediatrics* 2014;134:e1244–e1256

INTRODUCTION

Pediatricians play an important role in adolescent pregnancy prevention and contraception. Nearly half of US high school students report ever having had sexual intercourse.¹ Each year, approximately 750 000 adolescents become pregnant, with more than 80% of these pregnancies unplanned, indicating an unmet need for effective contraception in this population.^{2,3} Although condoms are the most frequently used form of contraception (52% of females reported condom use at last sex), use of more effective hormonal methods, including combined oral contraceptives (COCs) and other hormonal methods, was lower, at 31% and 12%, respectively, in 2011.¹ Use of highly effective long-acting reversible contraceptives, such as implants or intrauterine devices (IUDs), was much lower.¹

Adolescents consider pediatricians and other health care providers a highly trusted source of sexual health information.^{4,5} Pediatricians' long-term relationships with adolescents and families allow them to ask about sensitive topics, such as sexuality and relationships, and to promote healthy sexual decision-making, including abstinence and contraceptive use for teenagers who are sexually active. Additionally, medical indications for hormonal contraception, such as dysmenorrhea, heavy menstrual bleeding or other abnormal uterine bleeding, acne, and polycystic ovary syndrome, are often uncovered during adolescent visits. A working knowledge of contraception will assist the pediatrician in both sexual health promotion and treatment of common

adolescent gynecologic problems. Contraception has been inconsistently covered as part of insurance plans. However, the Institute of Medicine has recommended contraception as an essential component of adolescent preventive care,⁶ and the Patient Protection and Affordable Care Act of 2010 (Pub L No. 111–148) requires coverage of preventive services for women, which includes contraception, without a copay.^{7,8}

SETTING THE STAGE

Confidentiality and Consent

In the setting of contraception and sexual health care, the American Academy of Pediatrics (AAP) believes that policies supporting adolescent consent and protecting adolescent confidentiality are in the best interests of adolescents. Accordingly, best practice guidelines recommend confidentiality around sexuality and sexually transmitted infections (STIs) and minor consent for contraception.^{9–11} The majority of states have specific laws regarding minor consent to contraception (see *State Minor Consent Laws: A Summary*¹² and the Guttmacher Institute's State Center¹³ at <http://www.guttmacher.org/statecenter/> for regularly updated state-by-state summaries). For states without specific laws, best practice guidelines, federal statutes, and federal case law may support minor confidentiality and consent.¹² For example, family planning clinics funded by Title X of the federal Public Health Services Act (42 USC §§300–300a-6 [1970]) are required to provide confidential services to adolescents.¹²

The Health Insurance Portability and Accountability Act (HIPAA [Pub L No. 104–191, 1996]) specifically addresses minor confidentiality. Although HIPAA allows parents access to a minor's records as personal representatives, that access is denied when the minor is provided with confidentiality under state or other laws or when the parent agrees that the minor may have confidential

care.¹⁴ Therefore, the AAP recommends that pediatricians have an office policy that explicitly describes confidential services and that pediatricians discuss (and document) confidentiality with all parents and adolescents. As an additional protection for minors' confidentiality, HIPAA states that if there is no applicable state law about the rights of parents to access the protected health information of their children, pediatricians (or other licensed health professionals) may exercise their professional judgment to provide or deny parental access to the records.¹⁴ This can be accomplished with careful documentation of their professional judgment. Insurance, billing, and electronic health record systems create additional challenges, including maintaining the confidentiality of visits, visit content, associated laboratory test results, and payment for the contraceptive method itself.¹⁵ For additional discussion of electronic health records, see the AAP policy statement on health information technology.¹⁶

Careful attention to minor consent and confidentiality is important, because limitations on confidentiality and consent are linked to lower use of contraceptives and higher adolescent pregnancy rates.^{17–21} Parents need not be adversaries; in fact, many parents are supportive of minor consent and confidentiality for sexual health services.^{22,23} As permitted by law, adolescent contraception should be provided as a confidential service, with adolescents encouraged to involve parents or trusted adults as they are able.

Sexual History Taking and Counseling

Bright Futures recommends that pediatricians take a developmentally targeted sexual history, assess STI and pregnancy risk, and provide appropriate screening, counseling, and, if needed, contraceptives.²⁴ Key to history taking is an

honest, caring, nonjudgmental attitude and a comfortable, matter-of-fact approach to asking questions. This can be accomplished by assessing the 5 Ps of sexual history taking, as described by the Centers for Disease Control and Prevention (CDC): partners, prevention of pregnancy, protection from STIs, sexual practices, and past history of STIs and pregnancy.²⁵ Counseling should draw on motivational interviewing approaches, with the focus of the interview on future goals, belief in the adolescents' capacity to change, and engagement of the adolescent in the process of adopting health-promoting behaviors.²⁶ For an example of motivational interviewing for sexual health counseling, see Ott et al (2007),²⁷ and for a more detailed discussion of counseling approaches, see the accompanying technical report.²⁸

Counseling About Abstinence and Contraception

Counseling about abstinence and postponement of sexual intercourse is an important aspect of adolescent sexual health care. Abstinence is 100% effective in preventing pregnancy and STIs and is an important part of contraceptive counseling. Adolescents should be encouraged to delay sexual onset until they are ready. However, existing data suggest that, over time, perfect adherence to abstinence is low (ie, many adolescents planning on abstinence do not remain abstinent).^{29,30} Therefore, pediatricians should not rely on abstinence counseling alone but should additionally provide access to comprehensive sexual health information to all adolescents. For sexually active adolescents, including gay and lesbian adolescents,³¹ and those considering initiation of sexual activity, counseling additionally includes initiating contraception, supporting adherence to the contraceptive method, managing adverse effects, and providing periodic screening for STIs.²⁴

METHODS OF CONTRACEPTION

This section summarizes the contraceptive options for adolescents; the accompanying technical report provides more detailed information on each of the methods. When comparing the efficacy of different methods, it is important to distinguish between typical use and perfect use, and counseling should be based on typical use. Typical use efficacy refers to the probability of pregnancy during the first year of typical use and includes users with varying degrees of adherence; perfect use efficacy is the probability of pregnancy if used consistently and correctly every time.³² The most effective methods rely the least on individual adherence; for these methods, typical use effectiveness approaches perfect use effectiveness. Contraceptive methods most commonly used by adolescents are listed below, ordered from most to least effective, starting with long-acting reversible contraception (LARC): implants and IUDs. *Pediatricians are encouraged to counsel adolescents in that order, discussing the most effective contraceptive methods first* (see Table 1 for contraceptive effectiveness).

Progestin Implants

Implanon and Nexplanon (Merck, Whitehouse Station, NJ) are both single-rod implants that contain etonogestrel, the active metabolite of the progestin desogestrel. Implants, a LARC method, are highly effective, with typical and perfect use failure rates of less than 1%^{32,33}; they may remain in place for 3 years. The implant is inserted into the inside of the upper arm by a clinician who has completed the requisite training. Implants are ideal for adolescents who prefer a method that does not require regularly scheduled adherence and who desire an extended length of protection. A common reason for discontinuation is unpredictable bleeding or spotting.^{34,35}

TABLE 1 Contraceptive Method Efficacy

Method	% of Women Experiencing an Unintended Pregnancy in the First Year of Use		% of Women Continuing Use at 1 Year ^a

—, data not available.

^a Among couples attempting to avoid pregnancy, the percentage who continue to use a method for 1 y.

^b Among typical couples who initiate use of a method (not necessarily for the first time), the percentage who experience an accidental pregnancy during the first year if they do not stop use for any other reason. Estimates of the probability of pregnancy during the first year of typical use for spermicides, withdrawal, periodic abstinence, the diaphragm, the male condom, the pill, and Depo-Provera are taken from the 1995 and 2002 National Survey of Family Growth, corrected for underreporting of abortion; see the text for the derivation of estimates for the other methods.

^c Among couples who initiate use of a method (not necessarily for the first time) and who use it perfectly (both consistently and correctly), the percentage who experience an accidental pregnancy during the first year if they do not stop use for any other reason.

Contraceptive implants can also be offered to pregnant adolescents and provided in the immediate postpartum period, while the adolescent is still in the hospital. The American College of Obstetricians and Gynecologists (ACOG) and the CDC both support immediate postpartum insertion of implants as a safe and effective practice that removes barriers to care.^{36,37} The main theoretical concern about contraceptive implant use in the postpartum period is whether the progestin might have some effect on breastfeeding; however, studies of contraceptive implant use among breastfeeding women have generally found no effects on breastfeeding performance or infant health and growth.^{38,39} When starting an implant, patients should be counseled that a backup method (ie, condoms or abstinence) should be used for at least

the first week for contraceptive efficacy and that a condom should be used at all times for protection against STIs.

IUDs

IUDs inserted into the uterus also provide long-acting reversible contraception. Three IUDs currently are approved in the United States: 2 levonorgestrel-releasing T-shaped IUDs (Mirena, 52 mg levonorgestrel, and Skyla, 13.5 mg levonorgestrel; Bayer HealthCare Pharmaceuticals Inc, Wayne, NJ) and a copper-containing T-shaped IUD (Copper T380-A, ParaGard; Teva North America, North Wales, PA). The 13.5-mg levonorgestrel IUD is approved for 3 years,⁴⁰ the 52-mg levonorgestrel IUD is approved for 5 years,⁴¹ and the copper IUD is approved for 10 years.⁴² Despite their low but increasing use in the United

States, IUDs are used extensively worldwide because they are safe and effective methods of contraception with typical and perfect use failure rates of less than 1%.⁴³ The copper IUD can be used as emergency contraception (EC) within 5 days of unprotected intercourse.^{43,44}

Despite past concerns, IUDs are now known to be safe for nulliparous adolescents. IUDs themselves do not cause tubal infertility in nulliparous women,⁴⁵ and studies support a rapid return to fertility after IUD removal.^{46,47} The risk of pelvic infection with IUDs occurs only during insertion. Beyond the first 21 days, IUDs do not increase rates of STIs or pelvic inflammatory disease (PID).^{48,49} Unless the adolescent is at very high risk for STIs (eg, had sex with a partner with known gonorrhea), screening for gonorrhea and chlamydia can be performed on the day of insertion.⁵⁰ Treatment, if needed, can be subsequently provided without IUD removal, because studies have demonstrated that, provided the patient improves with treatment, both STIs and PID can be treated with the IUD in place.^{51,52} Contraindications to IUD placement are limited to current purulent cervicitis, gonorrhea, or chlamydia, current PID and other current pelvic infections (see “US Medical Eligibility Criteria for Contraceptive Use” for more extensive discussion).³⁷ Past PID is not a contraindication to IUD use. HIV infection and immunosuppression are also not contraindications to IUD use.

IUDs can also be offered to pregnant adolescents and provided in the immediate postpartum period, while the adolescent is still in the hospital. Two systematic reviews concluded that immediate postpartum insertion of IUDs is safe and effective,^{53,54} and both ACOG and the CDC support this practice.^{36,37,55} Studies have shown that many women who desire an IUD at the time of delivery do not return for later insertion and

that immediate insertion of IUDs provides similar contraceptive coverage as delayed insertion, even with higher expulsion rates with immediate insertion.^{56,57}

The emerging adolescent-specific data on IUDs are promising. However, there are some disadvantages. The limited data in adolescents suggest that expulsion, which occurs in fewer than 5% of women using IUDs, may occur more frequently in younger women.⁵⁸ Another concern is that more than half of young nulliparous women report moderate to severe pain with insertion.^{59,60} Nonetheless, studies demonstrate IUD continuation rates in adolescents that exceed those with other hormonal methods and effective use of the levonorgestrel IUD for menstrual suppression in adolescent patients with complex medical conditions.^{61–67}

Progestin-Only Injectable Contraception

Depot medroxyprogesterone acetate (DMPA, also known by the brand name Depo-Provera; Pfizer, New York, NY) is a long-acting progestin that is given as a single injection every 13 weeks (up to 15 weeks) using a dose of either 150 mg delivered intramuscularly or 104 mg delivered subcutaneously. Many health care providers schedule visits every 11 to 12 weeks for adolescents to allow for missed or delayed visits. Both regimens have similar effectiveness and side effects⁶⁸ and are highly effective in preventing pregnancy. In the first year of use, the probability of becoming pregnant with typical use is approximately 6%.³² DMPA can be initiated on the same day as the visit (“mid-cycle” or “quick” start) as long as the health care provider is reasonably certain the adolescent is not pregnant. For additional details, see the accompanying technical report and the CDC’s 2013 “US Selected Practice Recommendations for Contraceptive

Use.”⁵² When starting DMPA, patients should be counseled that a backup method (eg, condoms or abstinence) should be used for at least the first week for contraceptive efficacy and that a condom should be used at all times for protection against STIs.

DMPA is convenient for many adolescents because of its ease of use. Other advantages include improvement in dysmenorrhea and protection against iron deficiency anemia and endometrial cancer.⁶⁹ DMPA is safe for most patients with chronic illness,³⁷ is thought to raise the seizure threshold in adolescents with epilepsy,⁷⁰ and may decrease sickle cell crises.^{71,72}

The major disadvantages of DMPA include the need for an injection every 13 weeks and the menstrual cycle irregularities that are present for nearly all patients initially. These menstrual irregularities typically improve over time^{73,74} and may be less likely to result in discontinuation if patients are counseled about these effects before the first injection.^{75,76} Other possible adverse effects include headache, mastalgia, hair loss, change in libido, and weight gain. Studies in both adolescents⁷⁷ and adults⁷⁸ suggest that weight gain status at 6 months is a strong predictor of future excessive weight gain with ongoing DMPA use, but that weight gain does not occur in all patients.^{79,80}

DMPA causes reductions in bone mineral density (BMD),^{81–83} and in 2004 the US Food and Drug Administration (FDA) issued a black-box warning about the risk of decreased BMD among DMPA users.⁸⁴ Subsequent publications document a substantial recovery of BMD after the patient discontinues DMPA,^{85–87} and ACOG, recognizing the risk of unwanted pregnancy if women’s contraceptive options are limited, does not advise limiting DMPA use to 2 years (in contrast to earlier concerns⁸⁸) or routinely monitoring bone density after that time frame.⁸⁹ Nonetheless, it remains

important to consider other risk factors for osteoporosis and to tailor counseling and recommendations to each patient. All patients should be counseled about measures that promote skeletal health, such as daily intake of 1300 mg of calcium and 600 IU of vitamin D and regular weight-bearing exercise.⁹⁰

Combined Oral Contraceptive Pills

COCs are the most popular method of hormonal contraception for adolescents. COCs all contain a progestin and an estrogen. In almost every pill, the estrogen component is ethinyl estradiol in amounts varying from 10 to 50 µg. Many adolescent medicine experts begin with a COC containing 30 to 35 µg of ethinyl estradiol and a progestin such as levonorgestrel or norgestimate. However, any “low-dose” pill (ie, containing ethinyl estradiol 35 µg or less) can be used. Although inspection of the external genitalia and a vaginal swab or urine screen for STIs are recommended practices in the care of sexually active patients,⁹¹ no gynecologic examination is needed to determine eligibility for COC use. Like other combined methods including the contraceptive vaginal ring and transdermal patch, COCs can be started on the same day as the visit (“quick start”) in healthy, nonpregnant adolescents. Patients should be counseled that a backup method (ie, condoms or abstinence) should be used for at least the first 7 days for contraceptive efficacy and that a condom should be used at all times for protection against STIs. The CDC recommends prescribing up to 1 year of COCs at a time.⁵² Additionally, a routine follow-up visit 1 to 3 months after initiating COCs is useful for addressing adverse effects or adherence issues.

COCs have few contraindications in healthy female adolescents. They should not be prescribed for patients with severe and uncontrolled hypertension (systolic pressure ≥ 160 mm Hg or

diastolic pressure ≥ 100 mm Hg), ongoing hepatic dysfunction, complicated valvular heart disease, migraines with aura or focal neurologic symptoms, thromboembolism or thrombophilia, complications of diabetes (ie, nephropathy, retinopathy, neuropathy, or other vascular disease), and complicated solid organ transplantation.³⁷ The most serious adverse event associated with COC use is the increased risk of blood clots, which increases from 1 per 10 000 to 3 to 4 per 10 000 woman-years during COC use.^{92,93} In comparison, the incidence of venous thromboembolism associated with pregnancy and postpartum is 10 to 20 per 10 000 woman-years, of which 1% to 2% are fatal.^{94,95} Although smoking should be discouraged, it is not a contraindication to COC use in teenagers and adults younger than 35 years old.³⁷

Patients should be informed that common transient adverse effects of COCs include irregular bleeding, headache, and nausea. Recommendations for managing adverse effects have been published elsewhere⁹⁶ or can be found online (<http://www.managingcontraception.com/qa/index.php> or http://www.cdc.gov/mmwr/preview/mmwrhtml/rr6205a1.htm?s_cid=rr6205a1_w).⁵² Drug interactions should also be avoided. With medications that decrease COC effectiveness (eg, anti-convulsants and antiretroviral drugs), patients may benefit from choosing an alternative method or dosing⁹⁷ (see the accompanying technical report for additional details). Most broad-spectrum antibiotics (rifampin is an exception) do not affect the contraceptive effectiveness of COCs.³⁷

Typical use failure rates are 9% in adults and may be higher in adolescents.^{32,98} Counseling should include strategies to promote daily adherence, such as cell phone alarms and support from a family member or partner. Patients should be instructed

on what to do if pills are missed. A missed pill should be taken as soon as it is remembered. If more than 1 pill in a row is missed, only the most recently missed pill should be taken as soon as possible, and the remaining pills should be taken at the usual time. Patients should be reminded that 7 consecutive hormone pills are needed to prevent ovulation. Additional instructions can be accessed online (http://www.cdc.gov/mmwr/preview/mmwrhtml/rr6205a1.htm?s_cid=rr6205a1_w#Fig2).⁵² EC is indicated if 2 or more pills are missed in the first week of the cycle.^{99,100} EC should also be considered if 1 or more pills were missed earlier in the same cycle as a missed pill or late in the previous cycle (see online instructions provided earlier for details).

Many patients may benefit from decreasing or eliminating the hormone-free (placebo) interval. Extended or continuous cycles may be useful for treating medical conditions such as anemia, acne, severe dysmenorrhea, endometriosis, dysfunctional or heavy menstrual bleeding, Von Willebrand disease, and other bleeding diatheses and for adolescents who prefer amenorrhea.¹⁰¹ These regimens may also be useful for conditions that can be exacerbated cyclically, such as migraine (without aura), epilepsy, irritable bowel syndrome, inflammatory bowel disease, and some psychiatric and behavioral symptoms¹⁰²; the most common adverse effect of extended or continuous cycles is unscheduled bleeding. Patients may be reassured to know that observational data indicate that COC use does not increase the risk of infertility or breast cancer¹⁰³ and that use of COCs for more than 4 years provides significant protection against endometrial and ovarian cancers.¹⁰⁴

Contraceptive Vaginal Ring

The vaginal ring (NuvaRing; Merck, Whitehouse Station, NJ) releases a combination

of estrogen and progestin and thus has the same eligibility criteria for use as COCs. As with COCs, a same-day start (“quick start”) can also be used with the vaginal ring. The ring is inserted in the vagina and stays in place for 3 weeks, with removal for 1 week to induce withdrawal bleeding, followed by insertion of a new ring. Patients should be instructed to insert a new ring after 7 days even if bleeding has not ceased.

The ring has comparable efficacy, risks, and benefits as other combined hormonal methods but provides the simplest regimen.^{32,105,106} Adverse effects are also similar, with the additional vaginal symptoms of discharge, discomfort, and problems related to the device (eg, expulsion).¹⁰⁷ The ring is an excellent method for extended use because, although labeled for 28 days of use, the rings contain sufficient medication to be used for up to 35 days¹⁰⁸ and thus can be replaced once every calendar month. Sexually active patients may be reassured to know that most men were not bothered by its presence, if it was noted at all.^{109,110}

Transdermal Contraceptive Patch

The combination hormone (estrogen and progestin) transdermal contraceptive patch (Ortho Evra; Ortho-McNeil Pharmaceutical, Raritan, NJ) is placed on the abdomen, upper torso, upper outer arm, or buttocks using 1 patch for each of 3 weeks in a row, followed by 1 week off the patch, during which a withdrawal bleed usually occurs. Typical use failure rates are similar to those of COCs at 9%.³² The FDA has identified increased estrogen exposure (1.6 times higher than with a low-dose COC¹¹¹) and a potential increased risk of venous thromboembolism with the patch^{112,113} (see accompanying technical report for more complete discussion).

The patch has comparable efficacy, benefits, eligibility criteria for use, and drug interactions as COCs; side effects are similar to those of other combined methods, with the addition of dislodged patches and skin effects, such as hyperpigmentation,^{114,115} contact dermatitis, and other irritation.¹¹⁶ The risk of pregnancy with correct (“perfect”) use of the patch is slightly higher for women who weigh more than 198 pounds than for women who weigh less (0.9% vs 0.3% in first 12 months of use).^{117,118}

Progestin-Only Pills

Progestin-only pills (also known as “mini-pills”) work primarily by thickening cervical mucus, not by inhibiting ovulation. Because very stringent adherence is necessary, their failure rate can be significantly higher than those of other combined hormonal and progestin-only methods (IUDs and contraceptive implants and injections). However, they provide an additional option for patients who have safety concerns about estrogen use (see accompanying technical report for additional details).³⁷

Male Condoms

The male condom is the most common contraceptive method used by adolescents, with up to 52% of female and 75% of male adolescents reporting condom use at last intercourse.¹ Advantages include male involvement in the responsibility for contraception, easy accessibility by minors without a prescription, and low cost. Latex condoms also reduce STI transmission, with consistent evidence for the reduction of gonorrhea, chlamydia, trichomoniasis,^{119–123} and hepatitis B and HIV transmission¹²⁴ and emerging evidence for the reduction of herpes simplex virus,^{125,126} human papillomavirus,^{127,128} and syphilis transmission.¹²⁹ However, condom use requires com-

mitment at every sex act, tends to drop off over time, and is influenced by individual, relationship, and broader social factors.^{130–133} Although the perfect use failure rate of condoms is 2%, the typical use failure rate is 18% for all users and can be higher among adolescents.³² The high typical use failure rate, coupled with the condom's high STI protection, has led to the recommendation for dual contraception: condoms plus a highly effective hormonal or other long-acting method. Instructions for condom use can be found in the accompanying technical report, and additional details are provided in the AAP policy statement on condoms.¹³³

Emergency Contraception

In the United States, EC is available as oral levonorgestrel; an oral progesterone receptor modulator; ulipristal acetate; high-dose combined estrogen–progestin oral contraceptive pills (the Yuzpe regimen); and placement of a copper IUD. Levonorgestrel EC is preferred to the Yuzpe regimen because of the superior adverse effect profile and effectiveness, which is up to 85%.^{44,134} Ulipristal acetate may have greater effectiveness than oral levonorgestrel at the end of the 5-day window of use, and its remaining effectiveness and adverse effect profile are similar to those of levonorgestrel.^{135,136} In addition, on the basis of recent data about lower efficacy of levonorgestrel EC, ulipristal may be more effective in people who weigh more than 165 pounds.^{137,138} Placement of a copper-bearing IUD is less commonly used for EC in adolescents but is the most effective EC method, with a failure rate of less than 1%.¹³⁹

The recommended dosage of levonorgestrel is a single 1.5-mg dose.^{134,140} It is available either as 2 pills (0.75 mg each) or as 1 pill (Plan B One-Step; Teva Pharmaceuticals, Petah Tikva, Israel). Levonorgestrel-based EC delays or inhibits ovulation and does not

appear to be effective once ovulation has occurred. If used inadvertently during early pregnancy, it is not teratogenic, only ineffective.¹⁴¹ Thus, a pregnancy test is not mandatory before levonorgestrel EC is prescribed.⁴⁴

Plan B One-Step is approved by the FDA as a nonprescription product for all women of childbearing potential.¹⁴² Generic versions are approved as a nonprescription product for women 17 years of age and older; however, proof of age is not required to purchase them. Providing EC in advance increases the likelihood of use when it is needed without increasing sexual or contraceptive risk-taking behavior.^{143,144} Therefore, EC should be prescribed or recommended in advance for use for up to 5 days after an event of unprotected intercourse.⁴⁴ Additional details on EC mechanisms and use can be found in the AAP policy statement on emergency contraception⁴⁴ and the accompanying technical report.

Withdrawal

Withdrawal, or coitus interruptus, is a method in which the male partner attempts to pull out his penis before ejaculation. Because 57% of female adolescents report using withdrawal,¹ pediatricians should ask about it. However, because of its limited effectiveness (22% failure rate among all users)³² and lack of STI protection, pediatricians should encourage adolescents to adopt more effective methods.

Other Methods

The female condom, periodic abstinence (fertility awareness or “the rhythm method”), vaginal spermicides, the cervical cap, and the diaphragm are methods less commonly used by adolescents. Additional descriptions are available in the accompanying technical report.

SPECIAL POPULATIONS

Adolescents With Disabilities and Medically Complex Illness

An estimated 16% to 25% of adolescents are identified as having special health care needs, including physical disability, developmental disability, and medically complex illness.¹⁴⁵ The improved survival of adolescents with medically complex illnesses, such as disabilities, chronic disease, HIV, and solid organ transplants, has prompted greater attention to quality-of-life issues. These issues, including adolescent interest in romantic and sexual relationships, are typically addressed by a pediatrician. Sexuality and sexual health care needs in this population are often overlooked, yet data demonstrate that, compared with healthy adolescents, adolescents with chronic illness have similar levels of sexual behaviors and sexual health outcomes (eg, STIs).^{146,147} In addition to pregnancy prevention, these adolescents may need menstrual suppression for heavy menstrual bleeding, bleeding disorders, or chemotherapy. Other patients may be using teratogenic medications and need contraception for that reason. Issues that arise include safety concerns with estrogen use, medication interactions, and complications from the underlying disease. The CDC has recently addressed the contraceptive needs of young women with medical conditions by publishing the “US Medical Eligibility Criteria for Contraceptive Use.”³⁷ Available online, this document summarizes the literature on safety and efficacy of different contraceptive methods by medical condition. Additional details on specific populations (eg, those with disabilities) are summarized in the accompanying technical report.

Adolescents With Obesity

The sexual health needs and sexual behaviors of adolescents with obesity are substantially similar to those of

their normal-weight peers.^{148,149} In addressing contraception, it is important to note that obesity and related endocrine effects can influence the efficacy and adverse effects profiles of contraceptives. For example, a small number of excess pregnancies were found among transdermal contraceptive patch users weighing more than 90 kg (198 lb).^{117,118} The World Health Organization and CDC report that data are limited and inconsistent about whether COC effectiveness varies by body weight or BMI.^{37,150–152} A common concern of both adolescents and providers is additional weight gain among adolescents with obesity after they start contraception. Data suggest that women with obesity are no more likely to gain weight with COCs, the vaginal ring, IUDs, or implants than normal-weight peers. In contrast, adolescents with obesity who used DMPA were more likely than nonusers with obesity, COC users with obesity, and normal-weight DMPA users to gain weight.⁸⁰

Increasing numbers of adolescents are having bariatric surgery procedures performed, and these patients need highly effective contraception. Post-surgery data reveal an improvement in fertility coupled with the potential for decreased contraceptive effectiveness through malabsorption, vomiting, and diarrhea.⁸⁶ Professional consensus statements recommend delaying pregnancy for at least 12 months after the procedure.¹⁵³ All contraceptive methods are safe for women with a history of bariatric surgery, with the exception of oral contraceptives for women who have undergone malabsorptive procedures.³⁷ There is increasing experience and success with the levonorgestrel IUD placed at the time of surgery.¹⁵⁴

ADHERENCE AND FOLLOW-UP

Frequent follow-up is important to maximize adherence for all methods of contraception and to promote and

reinforce healthy decision-making. Adolescents count on trusted health professionals, such as pediatricians, for support and problem solving around continuation and adherence. Regularly scheduled contraceptive follow-up visits should address use, adherence, adverse effects, and complications. Pediatricians can use motivational interviewing approaches to increase effective and consistent contraceptive use, including engaging parental support for contraceptive adherence, when possible. Follow-up visits should additionally include reassessment of relationships, sexual behaviors, contraceptive needs, STI surveillance and prevention, and other sexual health prevention measures, such as human papillomavirus immunization.

RECOMMENDATIONS

1. Pediatricians should counsel about and ensure access to a broad range of contraceptive services for their adolescent patients. This includes educating patients about all contraceptive methods that are safe and appropriate for them and describing the most effective methods first.
2. Pediatricians should be able to educate adolescent patients about LARC methods, including the progestin implant and IUDs. Given the efficacy, safety, and ease of use, LARC methods should be considered first-line contraceptive choices for adolescents. Some pediatricians may choose to acquire the skills to provide these methods to adolescents. Those who do not should identify health care providers in their communities to whom patients can be referred.
3. Despite increased attention to adverse effects, DMPA and the contraceptive patch are highly effective methods of contraception that are much safer than pregnancy. Pediatricians should continue to make them available to their patients.

tricians should continue to make them available to their patients.

4. Pediatricians should allow the adolescent to consent to contraceptive care and to control the disclosure of this information within the limits of state and federal laws. There are a number of supports for protecting minor consent and confidentiality, including state law, federal statutes, and federal case law. Pediatricians will need to be familiar with national best practice recommendations for confidential care and with the relevant minor consent laws in their states.
5. Pediatricians should be aware that it is appropriate to prescribe contraceptives or refer for IUD placement without first conducting a pelvic examination. Screenings for STIs, especially chlamydia, can be performed without a pelvic examination and should not be delayed.
6. Pediatricians should encourage the consistent and correct use of condoms with every act of sexual intercourse.
7. Pediatricians should have a working knowledge of the different combined hormonal methods and regimens, because these provide excellent cycle control both for contraception and medical management of common conditions, such as acne, dysmenorrhea, and heavy menstrual bleeding.
8. Pediatricians should remember that adolescents with chronic illness and disabilities have similar sexual health and contraceptive needs to healthy adolescents while recognizing that medical illness may complicate contraceptive choices.
9. Pediatricians should regularly update their adolescent patients' sexual histories and provide a confidential and nonjudgmental setting in which to

address needs for contraception, STI screening, and sexual risk reduction counseling for patients who choose not to be abstinent.

10. Pediatricians should allow sufficient time with their adolescent patients to address contraceptive needs using a developmentally appropriate, patient-centered approach, such as motivational interviewing. If necessary, arrangements should be made for a separate visit for contraceptive follow-up to increase adherence and monitor for adverse effects and complications.
11. Pediatricians can complement the skills and resources of the pediatric office by being aware of state or federally subsidized insurance programs and clinics that provide confidential and free or low-cost reproductive health care services and supplies, including contraception.

abstract

FREE

A working knowledge of contraception will assist the pediatrician in both sexual health promotion as well as treatment of common adolescent gynecologic problems. Best practices in adolescent anticipatory guidance and screening include a sexual health history, screening for pregnancy and sexually transmitted infections, counseling, and if indicated, providing access to contraceptives. Pediatricians' long-term relationships with adolescents and families allow them to help promote healthy sexual decision-making, including abstinence and contraceptive use. Additionally, medical indications for contraception, such as acne, dysmenorrhea, and heavy menstrual bleeding, are frequently uncovered during adolescent visits. This technical report provides an evidence base for the accompanying policy statement and addresses key aspects of adolescent contraceptive use, including the following: (1) sexual history taking, confidentiality, and counseling; (2) adolescent data on the use and side effects of newer contraceptive methods; (3) new data on older contraceptive methods; and (4) evidence supporting the use of contraceptives in adolescent patients with complex medical conditions. *Pediatrics* 2014;134:e1257–e1281

INTRODUCTION

Pediatricians play a key role in adolescent sexual health and contraception. Sexual health is an important part of adolescent anticipatory guidance and screening, and pediatricians' long-term relationships with adolescents and families allow them to help promote healthy sexual decision-making, including abstinence and contraceptive use. Additionally, medical indications for contraception, such as acne, dysmenorrhea, and heavy menstrual bleeding, are frequently uncovered during adolescent visits. A working knowledge of contraception will assist the pediatrician in both sexual health promotion as well as treatment of common adolescent gynecologic problems. This technical report provides the pediatrician with updated information on adolescent sexual behavior, guidelines for counseling adolescents, and an update on available methods of contraception. It is a companion to the policy statement "Contraception for Adolescents."¹

ADOLESCENT SEXUAL BEHAVIOR AND USE OF CONTRACEPTION

Sexual intercourse is common among adolescents. In 2011, 47% of high school students reported ever having had sex, and 34% reported having had sex in the previous 3 months.² For the pediatrician, this means that approximately half of their adolescent patients have engaged in sex,

many without adequate protection against pregnancy and sexually transmitted infections (STIs).

Unintended pregnancy is a serious adolescent morbidity, and use of effective contraception is one of the pillars of adolescent pregnancy prevention. Each year, approximately 750 000 adolescent girls become pregnant, and 82% of these pregnancies are unplanned.^{3,4} More than half of these pregnancies (59%) end in births, 14% end in miscarriages, and 27% end in abortion.³ From 1990 to the early 2000s, adolescent pregnancy rates declined markedly, and 86% of this decline was attributable to increased consistent contraceptive use (the remainder was attributed to delay of sexual activity).⁵ By 20 years of age, 18% of young women will have given birth, and this number is largely unchanged from 2002.⁶

The contraceptive method most commonly used by adolescents is the condom (96% of young women who have ever used a contraceptive reported previous condom use), followed by withdrawal (57%) (see Table 1). Among hormonal methods, experience with combined oral contraceptives (COCs) is most common (56%), followed by depot medroxyprogesterone acetate

(DMPA) injection (20%), the transdermal patch (10%), and the vaginal ring (5%). More than 13% of adolescents have ever used emergency contraception (EC), and 15% have ever used periodic abstinence. However, ever having used a method does not necessarily translate into consistent or current use. When a nationally representative sample of all 15- to 19-year-old adolescent girls were asked about current use (past 3 months), 28% reported any contraceptive use. The pill was most commonly used (15%), followed by condoms (6%), DMPA (3%), and withdrawal, the contraceptive ring, and the intrauterine device (IUD) (all approximately 1%). The transdermal patch was less than 1% (see Table 2). Experience with long-acting reversible contraception (LARC), such as IUDs and implants, has increased markedly in 15- to 19-year-olds over the past decade, with the bulk of the increase in the 18- to 19-year age range. By 2009, it was estimated that 4.5% of contraceptive use was an IUD or implant.⁴

SETTING THE STAGE: CONFIDENTIALITY, CONSENT, AND THE SEXUAL HISTORY

Sexual history taking and counseling about pregnancy prevention, including contraceptive use, are key Bright Futures objectives for the adolescent visit.⁷ The demands of these tasks can be managed by situating them in an adolescent's medical home. Because of pediatricians' ongoing relationships with adolescents and families, they are optimally suited for this role.⁷ The following sections outline the evidence base for key elements relevant to contraceptive care, including confidentiality and consent, sexual history taking, and counseling.

Confidentiality and Consent

In the setting of contraception and sexual health care, the American Academy of

Pediatrics (AAP) believes that policies supporting adolescent consent and protecting adolescent confidentiality are in the best interests of adolescents. Most states have specific laws regarding minor consent to contraception (see "State Minor Consent Laws: A Summary"⁸ and the Guttmacher Institute's State Center⁹ for regularly updated state-by-state summaries). For states without specific laws, best-practices guidelines, federal statutes, and federal case law may support minor confidentiality and consent.¹⁰ For example, family-planning clinics funded by Title X of the federal Public Health Services Act (42 USC §§300–300a-6 [1970]) are required to provide confidential services to adolescents.⁸

The Health Insurance Portability and Accountability Act (HIPAA [Pub L No. 104-191, 1996]) specifically addresses minor confidentiality. Although HIPAA allows parents access to adolescents' records as personal representatives of the minor, that access is denied when the minor can consent under state or other laws, or when the parent agrees that the minor may have confidential care.¹⁰ The AAP, therefore, recommends that pediatricians have an office policy that explicitly describes confidential services and that pediatricians discuss (and document) confidentiality with all parents and adolescents. As an additional protection for minors' confidentiality, HIPAA states that if there is no applicable state law about the rights of parents to access the protected health information of their children, pediatricians (or other licensed health professionals) may exercise their professional judgment to provide or deny parental access to the records. This can be accomplished with careful documentation of their professional judgment.

Insurance billing, electronic health record systems, and patient portals create additional challenges to maintaining the

TABLE 1 Lifetime Use (Ever-Use) of Contraception Among Sexually Experienced Women Aged 15 to 19 Years: United States, 2006 to 2010

Never had intercourse or no intercourse in 3 mo before interview	60.0
Had intercourse in 3 mo before interview	6.5

confidentiality of visits, visit content, and associated laboratory testing that will need to be considered. The AAP policy statement on electronic health records supports privacy policies consistent with state health care consent laws and best practices around sensitive health topics such as sexual behavior and contraception.¹¹

Importance of Confidentiality and Consent

Careful attention to minor consent and confidentiality are important, because confidentiality is a major concern of adolescents¹² and a reason for foregoing contraceptive care. In a nationally representative sample, adolescents most in need of confidential health services (eg, sexually active girls) were more likely to cite confidentiality as a reason for foregoing health care.¹³ Confidentiality concerns are heightened among adolescents from underrepresented minority groups^{14,15} and other groups at high risk of unintended pregnancy (eg, those involved with the juvenile justice system; lesbian, bisexual, and transgender; and lower-income youth).^{16,17} Many adolescents

are unaware they can obtain confidential health care,¹⁸ presenting a potential barrier to access to contraceptive services.

Limitations on adolescents' confidentiality and their ability to consent have been associated with lower use of contraceptive services and poor outcomes. Among minors attending family-planning clinics, young women reported that if parental notification were required for prescriptive contraceptives, only 1% would stop having vaginal sex, but 59% would stop using all clinic services.¹⁹ Among young African American women, fear of family finding out about sexual health services was a common reason to delay a first clinic visit for contraception.²⁰ On a population level, minors' capacity to consent to contraceptives has been associated with lower adolescent birth rates,²¹ and restrictions on minors' capacity to consent to contraceptives have been associated with higher birth rates.²²

Parents

The relationship among parents, confidentiality, and access is complex. Many parents are supportive of minor consent and confidentiality for sexual health services. In a national Internet-based survey, 66% of parents agreed that it was important for adolescents to have private time with physicians, and more than half (54%) of parents did not want doctors to disclose confidential information obtained from adolescents to parents.²³ Many parents are aware that their adolescents use confidential sexual health services. A national study of adolescent family-planning clinic clients revealed that 60% of adolescents reported that their parents were aware of their use of sexual health services.²⁴ Among adolescents whose parents were aware of their sexual health service use, 79% would continue to use the services, even if parental notification were required; however, among adolescents

whose parents were unaware of their sexual health services use, fewer than 30% would continue to use services.²⁴

Sexual History Taking and Counseling

Taking a Sexual History

Adolescents consider pediatricians and other health care providers a highly trusted source of sexual health and other confidential information.^{25,26} When pediatricians discuss sensitive topics with adolescents, instead of reporting discomfort, adolescents reported that the pediatrician understood their problems, eased their worries, and allowed them to make treatment decisions.²⁷ Best-practices guidelines require that the sexual history be taken with the adolescent alone.⁷ Key to history taking is an honest, caring, nonjudgmental attitude and a comfortable, matter-of-fact approach to asking questions. This can be accomplished by using the "5 Ps" tool of the Centers for Disease Control and Prevention (CDC): partners, prevention of pregnancy, protection from STIs, sexual practices, and past history of STIs and pregnancy (see <http://www.cdc.gov/std/treatment/SexualHistory.pdf>).²⁸

Contraceptive counseling should be developmentally targeted, because the sexual health and contraceptive needs of early adolescents differ markedly from those of middle and late adolescents. Even among same-age adolescents, there is often a wide range in adolescents' sense of themselves as a sexual being, their sexual experiences, and their interest and need for contraception. For example, a study of early adolescents described views and behaviors ranging from considering sex to be "nasty" and something best left to adults, to an intense curiosity about and initiation of sexual behaviors.²⁹ Bright Futures provides sample questions and guidance for a developmentally tailored sexual history.⁷

Counseling Using Motivational Interviewing

Increasing evidence from studies of adolescents suggests that individual counseling about contraception and sexual health topics is most effective using patient-centered approaches, such as motivational interviewing.^{30,31} Motivational interviewing can be used to address the ambivalence and discrepancies among adolescents' sexual and contraceptive behaviors, their sexual and relationship values, and future life goals. Key elements are (1) an empathetic and nonjudgmental interviewer with unconditional positive regard for the adolescent in a safe, nonthreatening environment; (2) engaging adolescents in their own behavior change; (3) asking adolescents about their goals, and helping them identify inconsistencies between their goals and current behavior; (4) "rolling with resistance," or avoiding direct confrontation when resistance is met, and waiting for adolescents to find their own answers rather than pointing them out; and (5) supporting adolescents' capacity to change.^{32,33} Motivational interviewing is a natural extension of youth development principles in its focus on goals and future orientation, belief in adolescents' capacity to change, and engagement of adolescents in the process of adopting health-promoting behaviors.³⁴

Motivational interviewing is accomplished through open-ended questions and careful listening.^{32,33} In the context of pregnancy prevention and sexual health promotion, discussions might explore the adolescent's reasons for becoming sexually active and the effect that sexual intercourse and unintended pregnancy may have on relationships with peers, parents, and significant others.³⁵ For example, does the adolescent believe that sex will deepen a relationship?³⁶ Or is sexual behavior or pregnancy considered a

marker for adulthood?³⁷ A motivational interviewing approach to contraceptive counseling might also focus on adolescents' goals (examples of goals linked to sexual decision-making include school completion, college, marriage, and childbearing³⁷), and how contraception and the delay of pregnancy might affect those goals.³⁵ An example of an inconsistency between goals and behaviors might be the adolescent who expresses a desire to graduate from high school and attend college but is frequently engaging in unprotected sex, putting her at risk for an unintended pregnancy.

A common concern of pediatricians is giving complex messages to adolescents: in the case of sexual behavior, the complex message is that a pediatrician would like to encourage abstinence but also is willing and able to provide appropriate counseling regarding sexuality and contraception. With motivational interviewing approaches, it is possible and appropriate for pediatricians to provide this type of complex message, because the focus is on the adolescents' values and relationships and related goals and discrepancies between goals and behaviors. Research suggests that adolescents are capable of understanding this type of complex message and, in fact, may disregard messages that they consider judgmental or overly simplified or that eliminate key health information.^{25,26} More detailed information on motivational interviewing with adolescents can be found in recent publications.^{35,38}

Abstinence Counseling in the Office Setting

Counseling about abstinence is an important component of sexual health care. When used consistently without exception, abstinence can be an effective means of contraception and STI prevention and is a viable strategy in the pediatrician's toolkit for reducing unintended pregnancy and STIs. It has

been estimated that approximately one-quarter of the decline in the adolescent pregnancy rates from 1995 to 2002 was attributable to the delayed initiation of sexual activity.⁵ Abstinence counseling should follow the motivational interviewing approaches described previously. A set of practical tips for abstinence counseling within an office-based setting has been published, and it uses a comprehensive motivational interviewing perspective.³⁵

When adhered to perfectly, sexual abstinence is 100% effective, making it an attractive choice for pregnancy prevention. However, many adolescents who practice abstinence do not adhere to the method 100% of the time (ie, they occasionally have vaginal-penile intercourse). Few data exist on actual effectiveness of abstinence (called "typical use," see explanation in *Methods of Contraception*)³⁹; however, existing data suggest that the effectiveness of abstinence for pregnancy and STI prevention over extended periods of time is likely low. For example, among adolescents reporting virginity pledges in the National Longitudinal Study of Adolescent Health, at 6-year follow-up (wave 3), 88% had engaged in sexual intercourse (most premarital), and 5% were infected with STIs.⁴⁰ Because of concerns about a low typical-use effectiveness of abstinence as a contraceptive method, it is critical for pediatricians to reassess intentions to remain abstinent at every visit and additionally to provide access to comprehensive sexual health information, including information about EC and condom use. Comprehensive information, including pregnancy prevention, should be provided to all adolescents, including those who identify as lesbian and gay, because they may have opposite-sex partners as well.¹⁷

METHODS OF CONTRACEPTION

Numerous reviews and recommendations for prescribing and managing

contraception are available (see, for example, *Contraceptive Technology*⁴¹ and the CDC's "US Selected Prescribing Recommendations for Contraceptive Use"⁴²). Additionally, there are online resources for prescribing contraceptives geared toward clinicians (see Table 3). The following section focuses on the appropriateness of various methods available for adolescents.

When comparing the efficacy of different contraceptive methods, it is important to distinguish "perfect use" and "typical use." Perfect-use efficacy refers to the probability of pregnancy if used consistently and correctly every time; data for perfect use come from clinical trials with very high levels of adherence.⁴³ Typical-use efficacy refers to the probability of pregnancy during the first year of typical use; data for typical-use efficacy come from national surveys that include users with varying degrees of adherence.⁴³ Thus, the typical-use efficacy rates reflect how well a contraceptive method works with an average user, factoring in mistakes, such as missed pills, forgotten condoms, or patches that are left on too long. Table 4 includes perfect- and typical-use data for all contraceptive methods. The individual methods appropriate for adolescents are addressed hereafter, discussed in order of effectiveness, starting with LARC. It is recommended that pediatricians use a "tiered" approach to contraceptive counseling, starting with the most effective methods.

Progestin Implants

Currently available progestin implant LARC methods include Implanon and Nexplanon (Merck, Whitehouse Station, NJ). Both consist of a single-rod implant that contains etonogestrel, the active metabolite of desogestrel; Nexplanon also contains barium sulfate to render it visible on radiography. The implant, highly effective with a failure rate of less than 1%,^{43,44} may remain in place for 3 years. It is inserted into the inside of the nondominant upper arm, 6 to 8 cm above the elbow, by a medical professional who has completed the requisite training. Insertion takes approximately 1 minute, and removal can be accomplished in under 5 minutes.⁴⁵ Complications are rare but include transient nerve injury and the need for removal under general anesthesia.^{44,46,47} Implants are ideal for adolescents who prefer a method that does not require regularly scheduled adherence and who desire an extended length of protection. Authors in Brazil have identified it as a viable option for delaying second pregnancy in adolescent mothers.⁴⁸ In Australia, a prospective study was conducted of 137 adolescent mothers, 18 years or younger.⁴⁹ Participants selected their own method, with half choosing the implant and the remainder choosing COCs, DMPA, a barrier method, or nothing. Both method continuation and time to next pregnancy were significantly longer in implant users. It must be noted, however, that there were key differences be-

tween the users of the implant and users of other methods. For example, implant users were significantly more likely to be living with the birth father rather than one of their own parents. In addition, more than half of implant users discontinued their method earlier than 24 months, with the most common reason being abnormal uterine bleeding. This is consistent with observational studies (as opposed to clinical trials, which tend to enroll and retain more adherent contraception users) describing continuation rates and bleeding patterns in adult users.^{50,51} In a published summary of 11 clinical trials that included a total of 942 women within 80% to 130% of their ideal body weight, 64% reported amenorrhea or infrequent bleeding over the first 2 years, and 15% reported frequent or prolonged bleeding.⁵² This may differ from clinicians' anecdotal experience in part because heavier women may have more bleeding than lighter women.⁵³ Unlike most other continuous methods, it is not clear that implant users experience improved bleeding patterns over time.⁵⁴ Experience in the first 3 months may help predict future bleeding patterns,⁵³ but individual experience is highly variable. Although bleeding is frequent with all progestin-only methods, it is important to remember that unscheduled bleeding can also be a sign of an STI, and adolescents should be tested accordingly. Data are limited, but experts have recommended the use of nonsteroidal anti-inflammatory drugs and/or COCs

as potentially helpful measures to manage implant-related bleeding.⁵⁴

Other than irregular bleeding, adverse effects are not common, but include emotional lability, weight gain, headache, and acne.⁵² Data are scant on the effect of the implant on bone mineral density (BMD).^{55–57} Given the higher estradiol level in implant users compared with DMPA users,⁵⁴ it could be presumed that the implant has less effect on BMD, but this has not been adequately assessed in adolescent women. Similar to the combined hormonal methods, efficacy is impaired by hepatic enzyme-inducing drugs (see Table 5); however, implants are considered safe for women with estrogen contraindications.⁵⁸

For adolescents who need highly effective contraception that is user- and coitus-independent, the implant is an

outstanding choice. However, it is critical that the risk of persistent irregular bleeding is well understood; to date, this is the most common complaint resulting in premature removal. For adolescents seeking hormonal methods specifically to manage abnormal uterine bleeding and irregular cycles, a combined method or a levonorgestrel IUD may be more acceptable to the patient.

Intrauterine Contraception

IUDs are inserted into the uterus to provide long-acting reversible contraception. Appropriate for adolescents, IUDs are generally safe, effective methods of contraception with a failure rate of less than 1% (see Table 4).⁴³ Three IUDs currently are approved for the US market: a copper-containing T-shaped IUD (copper T380-A, ParaGard; Teva

North America, North Wales, PA) and 2 levonorgestrel-releasing T-shaped IUDs (52-mg levonorgestrel, Mirena, and 13.5-mg levonorgestrel, Skyla; Bayer HealthCare Pharmaceuticals Inc, Wayne, NJ). The primary mechanism of action of both types of IUD is preventing fertilization by inhibiting sperm motility. The levonorgestrel IUDs also thicken cervical mucus. All mechanisms occur before implantation, when pregnancy begins, and inhibiting implantation is not believed to be a primary mechanism of action for either type of IUD.⁵⁹ The 13.5-mg levonorgestrel IUD is approved for 3 years.⁶⁰ The 52-mg levonorgestrel IUD is approved for 5 years,⁶¹ although data suggest that it is still effective at least up to 7 years; similarly, the copper T380-A IUD is approved for 10 years,⁶² but data support use for 12 years.⁶³ Although IUDs have very low use in the United States, they are used extensively worldwide, and use is increasing in the United States, particularly among older adolescents.⁶⁴

Previous concerns about adolescents and IUDs have been addressed by more recent data demonstrating that IUDs are safe for nulliparous adolescents. For example, a case-control study demonstrated that past associations between infertility and IUD use among nulliparous women were attributable to STIs rather than IUDs.⁶⁵ Other studies support a rapid return to fertility after IUD removal.^{66,67} Data also address concerns about pelvic infections. There is a small increase in infection risk around the time of IUD insertion as a result of the procedure. However, beyond the first 20 days after insertion, IUDs do not increase rates of pelvic inflammatory disease (PID) above baseline.^{68,69} Screening for gonorrhea and *Chlamydia* can be performed at the same time as insertion.⁵⁹ Any necessary treatment can be subsequently provided without IUD removal, as international studies have demonstrated that STIs

and PID can be treated with the IUD in place,⁷⁰ as long as the patient improves with treatment. As a result, there are now more limited infectious contraindications to IUDs. These include current or recent (past 3 months) PID or current gonorrhea, *Chlamydia*, or purulent cervicitis. Additional contraindications include pregnancy and uterine anomalies that distort the uterine cavity in a manner incompatible with IUD insertion (see CDC recommendations for complete list⁵⁸). HIV infection and immunosuppression are not contraindications to IUD use.

The one area with less clarity is that, for insertion of IUDs (but not continuation), "high risk of STIs" is considered by the CDC to be level 2 (benefits generally outweigh risks) or level 3 (risks generally outweigh benefits, but clinician may individualize). However, the data supporting the level 3 categorization are from a study of HIV-infected adult women in Africa.⁵⁸ Beyond STI risk, existing concerns about IUD use in adolescents are that rates of expulsions

and experiences of pain and discomfort are somewhat higher among nulliparous compared with parous young women. Nonetheless, current data suggest that IUDs are generally well tolerated in young women and that continuation and satisfaction rates are high.⁷¹⁻⁷⁴

Adolescent-specific data are limited on acceptability and use of IUDs for contraception; however, recent studies are promising, suggesting 1-year continuation rates of 75% or greater.⁷⁵⁻⁷⁸ The data on levonorgestrel IUD use for medical indications in adolescents reveal improvement in dysmenorrhea and heavy menses.^{76,79} The levonorgestrel IUD is also useful for adolescents with medical conditions that require long-term menstrual suppression in which estrogen is contraindicated or that present a serious risk to the fetus in the case of unintended pregnancy. For example, use of the levonorgestrel IUD with disabled nonambulatory adolescents allows effective menstrual suppression while avoiding both exogenous estrogen exposure and the bone-density effects of DMPA.^{78,80} Levonorgestrel IUDs also provide an important option for adolescent bariatric surgery patients, for whom experts recommend a delay of pregnancy of at least 12 to 18 months after surgery but who often experience a rapid return to fertility after surgery.⁸¹ Barriers to pediatricians inserting IUDs, such as lack of training, lack of office capacity, or not seeing enough patient volume to maintain skills, pose an access problem, which can be overcome by identifying specific providers in the community to whom these patients can be referred.

Progestin Injections

DMPA, also known by the brand name Depo-Provera (Pfizer, New York, NY) is a long-acting progestin that is given as a single injection every 13 weeks (up to 15 weeks) using a dose of either 150 mg

delivered intramuscularly or 104 mg delivered subcutaneously; the feasibility of self-administration of the latter is currently under investigation. Both regimens have similar effectiveness and side effects.⁸² DMPA can be initiated on the same day as the visit ("mid-cycle" or "quick" start). The CDC states that even if pregnancy cannot be definitively ruled out, the benefits of initiating DMPA exceed the risks and that DMPA can be initiated at any time, with a follow-up pregnancy test in 2 to 4 weeks.⁴²

DMPA is highly effective in preventing pregnancy. In the first year of use, the probability of becoming pregnant by typical users is approximately 6% (perfect use is 0.2%; see Table 4).⁴³ Some experts believe that the use of DMPA, which first became available in the United States in 1992, is one factor responsible for the declining rates of adolescent pregnancy in the United States.^{5,83}

DMPA is convenient for many adolescents because of its ease of use compared with coitus-dependent methods or those that require daily, weekly, or monthly adherence. Other advantages, similar to combined hormonal methods, include improvement in dysmenorrhea and protection against iron-deficiency anemia and endometrial cancer.⁸⁴ DMPA may be safely recommended for adolescents who are lactating⁸⁵ and most of those who have chronic illnesses.⁵⁸ It may provide additional benefits in some circumstances, for example, by raising the seizure threshold⁸⁵ and decreasing sickle cell crises.^{87,88} Despite recent work suggesting that DMPA may result in an increased risk of venous thrombosis,⁸⁹ for patients at risk for estrogen-related complications, the advantages of DMPA are still believed to outweigh the risks.⁵⁸

The major disadvantages of DMPA for adolescents are menstrual cycle irregularities (present for nearly all patients initially), the need for an

injection every 13 weeks, and potential adverse effects, including weight gain and interference with normal increases in bone density. Other adverse effects include headache, mastalgia, hair loss, and change in libido. Although rare, anaphylaxis to DMPA has been described.⁹⁰

The irregular bleeding associated with DMPA typically improves over time.^{91,92} Studies have demonstrated that patients are more likely to continue DMPA use if they are counseled about adverse effects before their first injection, but these studies did not target adolescents specifically.^{93,94} Long-term DMPA use is also associated with a delayed return to fertility, typically 9 to 18 months, while the endometrial lining returns to its pre-DMPA state and ovulatory function returns. Both subcutaneous and intramuscular DMPA show similar delays to fertility after injection.⁹⁵ However, for adolescent patients, such a delay does not usually pose a major deterrent to using this method.

Although a number of observational studies have found an increased risk of weight gain among young women using DMPA,^{96–100} a recent Cochrane review¹⁰¹ evaluated this subject and identified only 2 high-quality and 2 moderate-quality studies, only one of which¹⁰² demonstrated that adolescents using DMPA had increased body fat percentage and decreased lean body mass. This finding, in contrast to widespread clinical observations about significant weight gain with DMPA, could be explained by significant variability in the trajectories of weight gain among women using DMPA. Bonny et al¹⁰³ studied 97 adolescents and found that 21% experienced early weight gain, defined as an increase in weight of more than 5% at 6 months. Over 18 months, those early gainers experienced an increase in mean BMI of 7.6 compared with 2.3 for non-early

weight gainers. Similar findings in adult patients¹⁰⁴ suggest that weight-gain status at 6 months is a strong predictor of future excessive weight gain with ongoing DMPA use but that weight gain on DMPA is not a uniform finding for all patients.^{96,98}

Because DMPA suppresses circulating estradiol concentrations, it causes lack of BMD accrual^{105–107} and has an adverse effect on biochemical markers of bone formation and resorption.¹⁰⁸ In response to these concerns, the Food and Drug Administration (FDA) issued a “black-box” warning regarding the risk of decreased BMD among DMPA users in November 2004.¹⁰⁹ The warning recommended using DMPA for longer than 2 years only if other methods are inadequate, noting a lack of certainty regarding peak BMD attained later in life among users of DMPA. Since that time, 3 publications have described prospective studies of adolescent and young adult women during and after use of DMPA.^{110–112} All 3 documented substantial recovery of BMD after DMPA use, thus, offering reassurance about the long-term skeletal health of adolescent patients who use DMPA. The American College of Obstetricians and Gynecologists, recognizing the risk of unwanted pregnancy if adolescents’ contraceptive options are limited, does not advise limiting DMPA use to 2 years, nor does it recommend monitoring BMD after that time frame.⁸³ In addition, some experts¹¹³ dispute the limited data that suggest a link between DMPA use and elevated risk of fractures in reproductive-age women^{114,115} and have called for removal of the black box warning.

Although recent studies are reassuring about the likelihood of bone recovery after DMPA cessation, it is important to consider other risk factors for osteoporosis and to tailor counseling and recommendations to each patient. Factors such as small

body habitus, chronic alcohol or tobacco use, eating disorders, or illness that necessitates chronic use of corticosteroids may lead a clinician to more strongly encourage alternatives to DMPA. All patients should be encouraged to include foods and/or supplements to ensure intake of at least 1300 mg calcium each day along with 600 IU vitamin D,¹¹⁶ to participate in weight-bearing exercise regularly, and to stop smoking as important measures to promote skeletal health. Clinicians must remind patients that, as with all hormonal methods of contraception, condoms should be used in conjunction with DMPA for protection from STIs.

Combined Oral Contraceptive Pills

COCs have been available for more than 50 years. They are a reliable, effective method for the prevention of pregnancy, are available only by prescription in the United States, and are the most popular method of hormonal contraception among adolescents (see Tables 1 and 2). They are the prototype for other combined methods of birth control, including the vaginal ring and transdermal patch (discussed later), which have similar effectiveness, contraindications, medical benefits, and side-effect profiles.

COC Prescribing

COCs all contain an estrogen and a progestin. In almost every pill, the estrogen component is ethinyl estradiol, in amounts varying from 10 to 50 µg, with “low-dose” pills (35 µg or less) being first-line options for adolescents. An internal pelvic examination is not needed before initiation of this method nor any other method except an IUD. However, routine screening for STIs is recommended in all sexually active patients. (For a more complete discussion of gynecologic examinations of adolescents in the pediatric office

setting, see the 2010 AAP clinical report on the subject.¹¹⁷) COCs can be started on the same day as the visit (“quick start”), or on the day following EC use (see section on EC) in healthy, non-pregnant adolescents. Patients should be counseled that a back-up method (ie, condoms or abstinence) should be used for at least the first 7 days for contraceptive efficacy, and a condom should be used at all times for protection against STIs. A routine follow-up visit 1 to 3 months after initiating COCs is useful for addressing persistent adverse effects or adherence issues.

There is no 1 pill formulation that is the best choice for every adolescent, and even within the “low-dose” range, changing the amount of estrogen or the type of progestin may be necessary to address adverse effects or optimize medical benefits. Patients also should be informed of common transient adverse effects, including irregular bleeding, headache, and nausea. Neither weight gain nor mood changes have been reliably linked to use of combined hormonal contraception.^{118–120} Recommendations for managing adverse effects have been published elsewhere¹²¹ or can be found online (<http://www.managingcontraception.com/qa/index.php>). COCs have few contraindications in healthy female adolescents. They should not be prescribed for patients with severe and uncontrolled hypertension (systolic pressure ≥ 160 mm Hg or diastolic pressure ≥ 100 mm Hg); ongoing hepatic dysfunction; complicated valvular heart disease; migraines with aura or focal neurologic symptoms; complications of diabetes (ie, nephropathy, retinopathy, neuropathy, or other vascular disease); complicated solid organ transplantation; or thromboembolism or thrombophilia (eg, factor V Leiden mutation; antiphospholipid antibody syndrome; or protein C, protein S, or antithrombin 3 deficiency).¹¹¹ An excellent and up-to-

date resource for prescribing hormonal contraceptives, the “US Medical Eligibility Criteria for Contraceptive Use,” is available on the CDC Web site (<http://www.cdc.gov/reproductive-health/UnintendedPregnancy/USMEC.htm>) and in print.⁵⁸ These recommendations weigh the risks and benefits of contraceptive methods against unwanted pregnancy. When hormonal methods are used for medical therapy, the risk/benefit ratio may differ, and treatment decisions should be considered on a case-by-case basis. Other useful resources include a 2004 detailed discussion of contraceptive choices for patients with congenital heart disease¹²² and a recent publication offering expert guidance on prescribing contraception to adolescents at increased risk of hypercoagulability.¹²³ The most serious adverse event associated with COC use is the increased risk of blood clot, which is discussed in further detail in the following paragraphs.¹²⁴ Although smoking should be discouraged, it is not a contraindication to COC use in teenagers and young adults.⁵⁸

New data have continued to emerge regarding the risks and benefits of different progestins. On April 10, 2012, the FDA posted a drug safety communication that resulted in revised drug labels for COCs containing the progestin drospirenone.¹²⁵ These note that epidemiologic studies reported as high as a threefold increase in the risk of blood clots for drospirenone-containing products when compared with products containing levonorgestrel or some other progestins, whereas other epidemiologic studies found no additional risk of blood clots with drospirenone-containing products.

However, it is important to remember that most of the risk of blood clot is conferred from the estrogen component of the pill and that all COCs confer a lower risk of blood clot than

pregnancy.¹²⁶ The baseline incidence of venous thromboembolism in adolescents is up to 1 per 10 000 woman-years per year.¹²⁷ Currently available COCs increase the risk of blood clot three- to fourfold, or up to 4 per 10 000^{123,124} woman-years. In comparison, the incidence of venous thromboembolism (VTE) associated with pregnancy and the postpartum period is 10 to 20 per 10 000 woman-years, of which 1% to 2% are fatal.^{128,129}

COCs decrease the effectiveness of some medications (eg, lamotrigine). Conversely, other medications, such as anticonvulsants and antiretroviral agents, decrease COC effectiveness to the extent patients may need to choose alternative methods¹³⁰ (see Table 5 and Special Populations). With regard to antibiotics, neither a 2001 review of the literature¹³¹ nor a 2011 case-crossover study of 1330 COC failures¹³² found any definitive evidence of decreased COC effectiveness with the use of any antibiotic except rifampin.

Used perfectly, COCs are extremely effective, with a perfect-use failure rate for all users of 0.3%; however, the typical-use failure rate is 9%, suggesting that adherence is a key issue in COC use (see Table 4).⁴³ Counseling should include strategies to promote adherence, such as cell phone alarms and support from a family member or partner. Patients should be instructed on what to do if pills are missed. A missed pill should be taken as soon as it is remembered. If more than 1 pill in a row is missed, only the most recently missed pill should be taken as soon as possible, and the remaining pills should be taken at the usual time, reminding patients that 7 consecutive hormone pills are required to prevent ovulation. Further instructions can be accessed online at http://www.cdc.gov/mmwr/preview/mmwrhtml/rr6205a1.htm?s_cid=rr6205a1_w#Fig2.⁴² Patients should also be advised that EC

may be needed if 2 or more pills are missed in the first week or if 1 or more pills were missed earlier in the same cycle or late in the previous cycle (see online instructions and Fig 1 for details).

COC Regimens

COCs are currently available in fixed-dose, monophasic regimens (each tablet contains the same dose of estrogen and progestin) or in phasic regimens (triphasic and biphasic packs that contain varying doses of estrogen and progestin). Standard pill packs include 28 pills total, with 21 to 24 hormone pills and 4 to 7 placebo (hormone-free) pills. Among low-dose pills, there are no clear data suggesting one formulation is superior to another for adolescent use, so it is appropriate to choose one with the lowest copay on a patient's insurance formulary (if applicable). Many experts recommend starting adolescents on a monophasic pill with monthly bleeding and then changing regimens and/or extending cycles, as indicated, to address patient adverse effects or preference.¹²¹ Many adolescent medicine providers begin with a COC containing 30 to 35 µg of ethinyl estradiol and a progestin, such as levonorgestrel or norgestimate.

The benefits of decreasing or eliminating the placebo hormone-free interval (see section on COC benefits) have been increasingly recognized, and there are several regimens packaged with more than 21 active pills and fewer placebo pills. For example, some regimens (eg, Yaz [Bayer, Leverkusen, Germany], and Generess FE [Watson, Parsippany, NJ]) have 24 active pills and 4 pills without hormones. Several brands are available with 84 active pills and 7 placebos, or 84 active pills and 7 pills of low-dose estrogen (eg, Seasonique and LoSeasonique; Teva, Petah Tikva, Israel). In 2007, the FDA approved the first COC packaged with a year of continuous combined hormone pills, Lybrel (Pfizer, New York, NY).

COC Benefits

The noncontraceptive benefits of COC use include decreased menstrual cramping and blood loss and improvement in acne. Extended or continuous cycles may be particularly appropriate for adolescents with medical conditions, such as anemia, severe dysmenorrhea, endometriosis, abnormal uterine bleeding, and Von Willebrand and other bleeding diatheses and for adolescents who prefer amenorrhea.¹³³ These regimens may also be useful for conditions that are known to be exacerbated cyclically, such as migraine (without aura), epilepsy, irritable bowel syndrome, some psychiatric symptoms,¹³⁴ and behavioral problems (such as increased aggression or self-mutilation) that sometimes worsen cyclically in young women with profound cognitive impairment.¹³⁵ The most common adverse effect of extended-cycle regimens is unscheduled bleeding. Eliminating the hormone-free interval will also minimize fluctuations in medications that interact with COCs (see section on Special Populations). In addition, ovarian suppression is optimized by COC regimens with shorter or no placebo (hormone-free) intervals, potentially increasing contraceptive effectiveness, especially among adolescents who frequently miss pills.^{136–138}

Families can be reassured that COC use has not been shown to increase the risk of breast cancer.¹³⁹ Also, use of COCs for more than 3 years provides significant protection against endometrial and ovarian cancers.¹⁴⁰ Overall, COCs are one of the best-studied medications ever prescribed. Completely reversible and with no negative effect on long-term fertility, COCs are a safe option throughout a woman's reproductive years.

Contraceptive Vaginal Ring

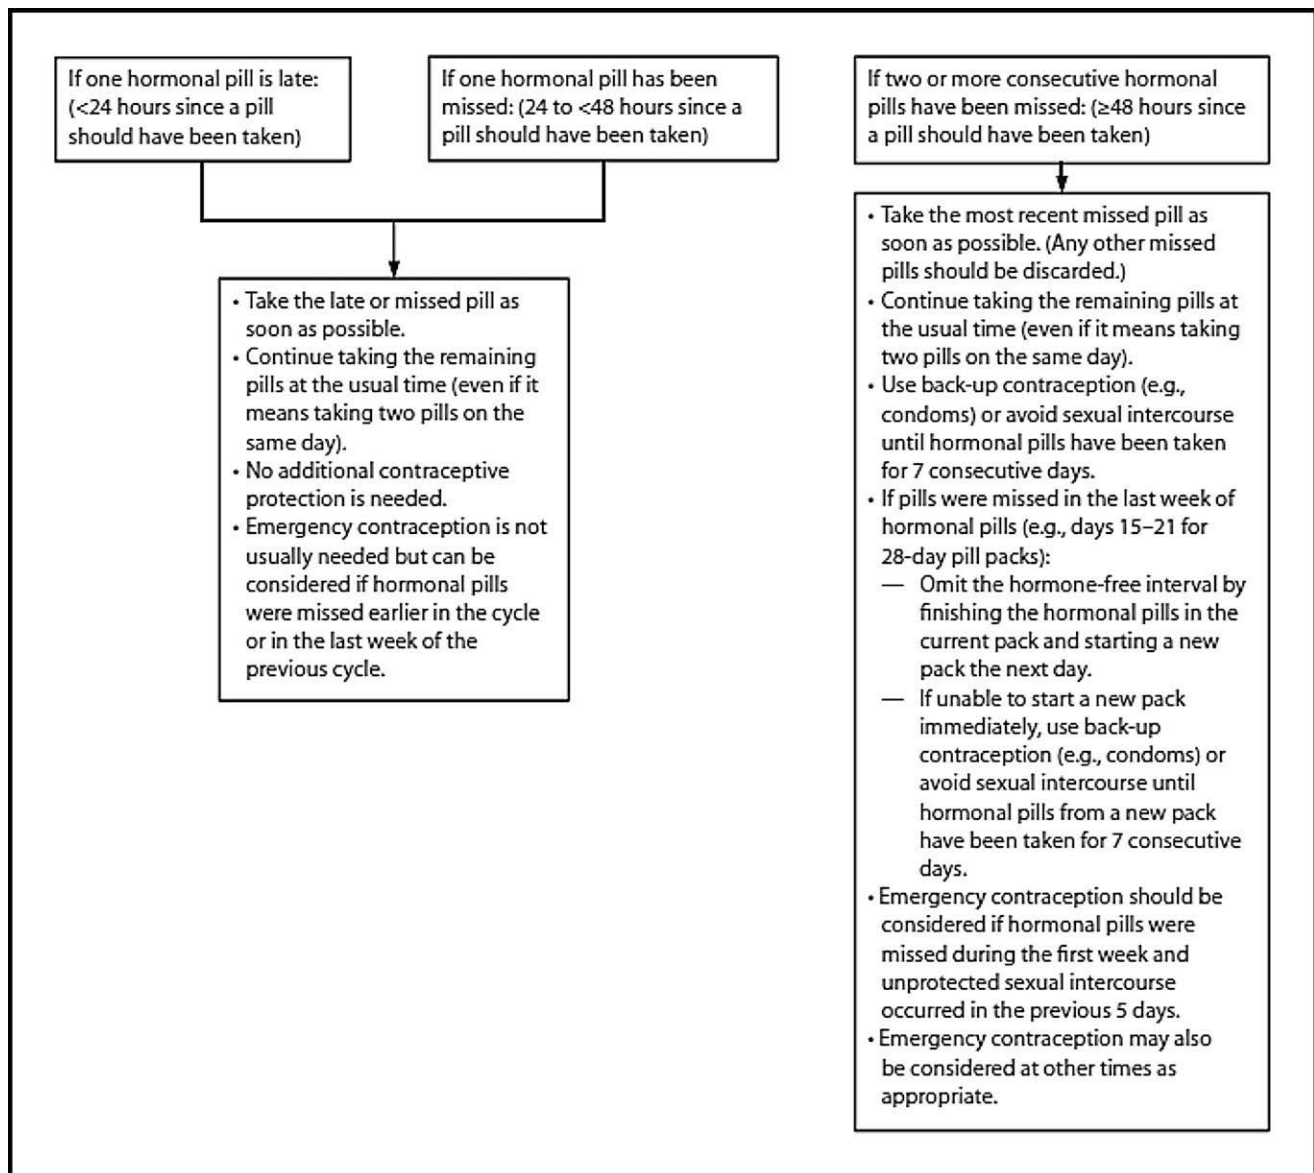

The vaginal ring (NuvaRing; Merck) releases 15 µg ethinyl estradiol and 120 µg etonogestrel (the active metabolite

of desogestrel) daily. It is a round, flexible device that measures 54 mm in outer diameter and 4 mm cross-sectionally. This soft silicone vaginal ring releases both estrogen and progestin hormones that protect against pregnancy for 1 month. It is inserted in the vagina and stays in place for 3 weeks, with removal for 1 week to induce menstruation followed by insertion of a new ring. Patients should be instructed to insert a new ring after 7 days even if bleeding has not ceased.

Because adolescents may be unfamiliar with their own reproductive anatomy, a pelvic model¹⁴¹ or other visual aid may be useful in explaining to patients where the ring will be. Patients should be reassured that the ring will not fall out. Eighty women (~90% of them nulliparous) were examined with the ring in place and none were able to expel the ring by bearing down in a Valsalva maneuver.¹⁴² The ring typically sits with the superior-most portion of the ring lying posterior to the cervix.¹⁴³

Most patients will not have previous experience with intravaginal medication and may have questions about its use, such as whether tampons can be worn when the ring is in place. On the basis of evaluation of serum concentrations of ethinyl estradiol and etonogestrel, contraceptive efficacy should not be compromised by concomitant use of tampons,¹⁴⁴ the spermicide nonoxonyl-9,¹⁴⁵ or intravaginal miconazole.¹⁴⁶ Similarly, the ring is intended to stay in place during coitus but can be removed for up to 3 hours if desired. This is not typically recommended, and sexually active patients may be reassured to know that most men were not bothered by its presence, if it was noted at all.^{142,147}

The ring has comparable typical-use failure rate (9%), risks, and benefits as other combined hormonal methods⁴³ but provides the simplest regimen.^{148,149} As with COCs, a same-day

**FIGURE 1**

Instructions for late and missed combined oral contraceptive pills.

start can be used with the vaginal ring. Adverse effects are largely similar to other combined methods, including breast tenderness, headaches, nausea, and breakthrough bleeding or spotting, with the additional vaginal symptoms of discharge, discomfort, and problems related to the device (eg, expulsion).¹⁵⁰ The limited investigation of bone health with the ring points to its bone neutrality, but these studies have not included adolescents younger than 18 years.^{151,152} Studies to date

have yielded inconsistent results about how the risk of VTE with use of the ring compares with the risk with use of low-dose COCs.^{153–156}

Analogous to experience with the contraceptive patch, it has not been clearly demonstrated that the simplified regimen afforded by the ring results in improved medication adherence or continuation in young people.¹⁵⁷ A trial of 237 college students randomized to use either the ring or COC found that perfect use was greater for the ring in

the first 2 months but that this was no longer statistically significant in the third month of the study. Similarly, 6-month continuation rates were no different and were less than 30% for both groups.¹⁵⁸

The ring is an excellent method for extended use. The vaginal ring package insert states that 1 ring can be used for up to 28 days with no back-up method; however, the rings contain sufficient medication to be used for up to 35 days¹⁵⁹ and, thus, can be replaced

once every calendar month. This eliminates the need for additional refills potentially not covered by insurers, which sometimes poses barriers to continuous pill and patch regimens. As with COCs, the longer the duration of continuous hormones, the greater the number of unscheduled bleeding days; however, the difference between a 28-day and 49-day cycle is small.¹⁶⁰ Similar to COCs, the decision about how often to allow uterine bleeding to occur can be individualized to the adolescent's medical needs and preferences. Women who choose to use the ring continuously with no planned ring-free days can be advised to remove the ring for 4 days if they have more than 5 days of consecutive bleeding, as this has been found to result in fewer bleeding days overall.¹⁶¹

Transdermal Contraceptive Patch

The combination hormone transdermal contraceptive patch (Ortho Evra [Ortho-McNeil Pharmaceutical, Raritan, NJ]) contains 0.6 mg norelgestromin and 0.75 mg ethinyl estradiol and measures approximately 1.75 × 1.75 in. The patch can be placed on the abdomen, upper torso, upper outer arm, or buttocks, using 1 patch for each of 3 weeks in a row, followed by 1 week off the patch, during which a withdrawal bleed usually occurs. Current estimates of failure rates for typical use are 9% (<1% for perfect use).⁴³ Approved by the FDA in November 2001, patch use rose in popularity until 2005, when use declined¹⁶² after publicity about increased estrogen exposure from the patch, which has been found to be 1.6 times higher than estrogen exposure with a COC.¹⁵³ The patch has undergone multiple label revisions, most recently August 22, 2012. The 2012 package insert contains a black box warning citing 5 US studies^{163–170} (1 with statistically significant findings) that suggest a possible increased risk of VTE compared with a 20- to 35-μg COC, with odds ratios

of 1.2 to 2.2. Although these potential health risks are concerning to some adolescents, the patch remains an important contraceptive alternative that may be the best option for some adolescents, especially in comparison with the many adverse consequences of unplanned pregnancy, which include an increased risk of VTE. Nonetheless, other methods may be safer first-line choices for patients interested in extended cycling.

The patch has comparable efficacy, benefits, and drug interactions as other combined methods, but provides a simpler regimen. Thus, it was initially assumed that the patch would promote improved contraceptive adherence in adolescents. Accordingly, early studies demonstrated better adherence to the patch than to COCs among adults,^{171,172} most notably among 18- and 19-year-olds,^{173,174} and 2 smaller studies of adolescents had high rates of self-reported short-term perfect patch use, 87% and 93%.^{175,176} However, contraceptive effectiveness requires that the method be sufficiently well accepted to be continued over time.

To our knowledge, there are no studies that have randomized adolescents to use either the patch or pills, and the observational studies that have compared these methods are plagued by possible selection bias; adolescents who choose a nondaily method may have behavioral characteristics that would interfere with continuation and perfect use of any method.^{177–179} For example, Bakhru and Stanwood¹⁷⁷ prospectively followed 1230 women (416 of whom were 17 years or younger) who self-selected their method and found 57% continuation of the patch at 1 year compared with 76% continuation of the pill ($P = .004$). In contrast to their initial hypothesis, patch users were significantly less likely than pill users to continue their method and, thus, were more likely to experience pregnancy.¹⁷⁷

Even lower rates of patch continuation, ranging from 25% to 50%, have been found in other longitudinal studies of adolescent patch users.^{179–181}

In addition, similar findings have been shown in randomized studies of adults. A 2010 Cochrane review¹⁸² (based on 4 such studies) concluded that patch users were more likely than pill users to discontinue study participation because of adverse effects. Similarly, in a study that randomized 500 women (average age, 25–26 years) to either the patch or the contraceptive vaginal ring, only 27% of patch users (versus 71% of ring users) planned to continue their assigned method after the 3-month study concluded.¹⁸³

Side effects of the patch are largely similar to other combined methods, with the addition of local adverse effects, such as dislodged patches and hyperpigmentation,^{175,176} contact dermatitis and other skin irritation,¹⁸⁴ and concerns about the visibility and appearance of the patch.^{185,186} Investigations into the patch's effect on bone health have yielded inconsistent results, with findings in adults^{150,151} more reassuring than those in adolescents.¹⁸⁷ However, this limited work is far from conclusive.

Progestin-Only Pills

Progestin-only pills (POPs, also known as “mini-pills”) work primarily by thickening cervical mucus, not by inhibiting ovulation. Because of the timing of this effect, it is generally recommended that pills be taken between 4 and 22 hours before coitus usually takes place. Perfect and typical-use failure rates for POPs are not calculated separately from those of combined hormonal contraceptives. Given the importance of even small variations in the timing of pill administration and the continued potential for ovulation, POPs are generally held to be less effective than combined hormonal methods.

Similar to other progestin-only methods, irregular bleeding is a common adverse effect. However, POPs are markedly less effective than other progestin-only methods, including the progestin-containing IUD, the progestin implant, and injectable progestin. Therefore, POPs are not typically recommended as a first-choice contraceptive in healthy adolescents. Nonetheless, they provide a progestin-only alternative for selected adolescent patients with demonstrated excellent medication adherence.

Male Condoms

The male condom is a mechanical barrier method of contraception and STI prevention. In a recent nationally representative survey, condom use was reported at first intercourse by 68% of adolescent girls and 80% of adolescent boys and at most recent intercourse by 52% of adolescent girls and 75% of adolescent boys.¹⁸⁸ Male condoms have several advantages for adolescents, including involving males in the responsibility of contraception, easy accessibility and availability to minors, use without a prescription, and low-cost STI protection.

Male condoms are most commonly made of latex. Lubricated condoms are used for vaginal and anal intercourse; unlubricated condoms are available for oral sex. Although many individuals will need additional lubrication with condoms, adolescents' lubricant use is rarely assessed. Condoms should be used only with water-based lubricants (eg, K-Y Jelly [McNeil PPC Inc, Fort Washington, PA], Astroglide [Biofilm Inc, Vista, CA]), because oil-based lubricants (eg, petroleum jelly, massage oils, body lotions) can weaken latex and cause breakage. Male condoms also are available as polyurethane (synthetic) for people with latex sensitivities and as natural membrane (eg, lamb cecum). Polyurethane condoms have similar effectiveness to latex condoms

but are more resistant to deterioration and are compatible with both oil- and water-based lubricants. Natural membrane condoms are porous and provide inadequate STI protection.

Condom effectiveness depends on consistent and correct use (see Table 6).¹⁸⁹ For pregnancy prevention, the failure rate at the end of first-year use for the male latex condom is 2% with perfect use and 18% with typical use.^{43,190} Consistent evidence supports condoms as reducing the risk of disease transmitted to and from the penile urethra, including gonorrhea, *Chlamydia*, trichomoniasis, hepatitis B, and HIV.^{191–195} Emerging evidence also supports condoms as reducing the risk of acquiring diseases transmitted through skin or mucosal contact, including genital herpes simplex virus,^{196,197} human papillomavirus,^{198,199} and syphilis.²⁰⁰ Because condoms protect against STIs, all sexually active adolescents should be encouraged to use condoms, regardless of whether an additional contraceptive method is used. Instructions for condom use can be found in Table 6. Additional details on condoms and recommendations can be found in the AAP policy statement on condom use by adolescents.²⁰¹ Despite increases in condom use, many adolescents do not use condoms effectively or at all. Condom use is influenced by individual, relationship, and broader social and structural factors,^{202–204} which should be addressed on multiple levels, including provider counseling, sex education, and interventions to improve access. Because condom use requires cooperation and communication between partners, condom use within relationships changes as relationships evolve²⁰⁵ and commonly declines in established relationships.^{206,207}

Emergency Contraception

In the United States, the available methods of EC include orally administered hormones, either in a progestin-

only dedicated EC product (levonorgestrel, 1.5 mg) or in high-dose combined estrogen and progestin oral contraceptive pills (the Yuzpe regimen); ulipristal acetate (a progesterone receptor modulator); and insertion of a copper IUD. These methods can prevent pregnancy when initiated up to 5 days after an act of underprotected sexual intercourse but are more effective the sooner they are used. Data suggest that ulipristal acetate, approved by the FDA in 2010, may have increased effectiveness over oral levonorgestrel at the end of the 5-day window of use and in heavier women.^{208–210} On the basis of data demonstrating that the levonorgestrel EC pill loses effectiveness in women who weigh more than 165 pounds and is ineffective in women who weigh more than 176 pounds, the levonorgestrel EC pill is undergoing revised labeling in Europe, and the FDA is considering whether to require similar revisions in the United States.²¹¹

Unlike ulipristal, which is pregnancy category X, levonorgestrel does not have teratogenic or other adverse effects on the fetus,²¹² and a pregnancy test is not necessary before prescribing levonorgestrel EC.²¹³ Levonorgestrel EC is estimated to be up to 85% effective.^{213,214} Additional details on prescribing EC can be found in the AAP policy statement on emergency contraception,²¹³ and additional guidance can be found at <http://ec.princeton.edu/questions/dose.html#dose>.

Plan B One-Step (Teva Pharmaceuticals, Petah Tikva, Israel), a dedicated progestin-only method, is approved by the FDA as a nonprescription product for all women of childbearing potential. Generic versions are approved as nonprescription for women 17 years of age and older; however, proof of age is not required to purchase them.

Given the barriers to EC access and the importance of timely use, advance prescription for EC should be a part of routine adolescent care.²¹³ There are

TABLE 6 How to Use a Condom Effectively

Before: Store condoms in a cool, dry place. Heat, including body heat from a pocket, can cause latex to degrade over time. Check the expiration date before use.

1. Use a new condom for every act of vaginal, anal, and oral sex throughout the entire sex act (from start to finish).
2. Before any genital contact, put the condom on the tip of the erect penis with the rolled side out.
3. If the condom does not have a reservoir tip, pinch the tip enough to leave a half-inch space for semen to collect. Holding the tip, unroll the condom all the way to the base of the erect penis.
4. After ejaculation and before the penis gets soft, grip the rim of the condom and carefully withdraw. Then gently pull the condom off the penis, making sure that semen does not spill out.
5. Wrap the condom in a tissue and throw it in the trash where others will not handle it.
6. If you feel the condom break at any point during sexual activity, stop immediately, withdraw, remove the broken condom, and put on a new condom.
7. Ensure that adequate lubrication is used during vaginal and anal sex, which might require water-based lubricants. Oil-based lubricants (eg, petroleum jelly, shortening, mineral oil, massage oils, body lotions, and cooking oil) should not be used, because they can weaken latex, causing breakage.

no medical contraindications to this method, and multiple studies have found that providing EC in advance increases the likelihood of women using it when it is needed and does not increase sexual or contraceptive risk-taking behavior.^{215,216} Given the sometimes sporadic and unplanned nature of adolescent sexual behavior, counseling and advance provision of EC should be a part of anticipatory guidance.

Other Barrier Methods

Female Condoms

The female condom is a polyurethane or synthetic nitrile pouch with 2 flexible rings, one fitting inside the vagina and the other on the perineum. Female condoms have a perfect-use failure rate of 5% and a typical-use failure rate of 21%.⁴³ Among US adolescents and young adults, the female condom

has had very low uptake,²¹⁷ in part because of higher cost, less availability, lack of knowledge, and negative attitudes toward female condoms.

Vaginal Spermicides

Vaginal spermicides are a chemical barrier method (most commonly nonoxynol-9) applied intravaginally through a variety of forms: gel, foam, suppository, or film. Spermicides consist of 2 components: a formulation (the gel, foam, suppository, or film) and the chemical ingredient that kills the sperm. Table 4 describes typical- and perfect-use failure rates for vaginal spermicides. The CDC identifies being at high risk for HIV (eg, commercial sex workers) and HIV infection as contraindications for use of spermicides, as use can disrupt the cervical mucosa, potentially increasing risk of HIV acquisition or increased viral shedding and transmission of HIV.^{58,218}

Diaphragm, Cervical Cap, and Contraceptive Sponge

The diaphragm, cervical cap, and sponge are barrier methods of contraception. They are less commonly recommended for adolescents, because they do not provide STI protection and have lower effectiveness rates than other methods.⁴³ Diaphragms are flexible latex cups used with spermicide that are inserted into the vagina before intercourse and must remain in place for 6 hours after intercourse. Cervical caps are latex or silicone cups with a firm rim that adhere to the cervix and provide continuous contraceptive protection for up to 48 hours. Sponges are polyurethane sponges that contain nonoxynol-9 spermicide. They are approximately 2 inches in diameter, can be inserted up to 24 hours in advance, and must be left in place for 6 hours after intercourse. Sponges are available over the counter. Diaphragms and caps require fitting by a health care pro-

fessional. Table 4 provides typical- and perfect-use failure rates for the diaphragm, cervical cap, and contraceptive sponge. For the sponge, typical- and perfect-use failure rates are as much as 16% and 11%, respectively.²¹⁹ These methods are contraindicated in women at high risk of HIV or women with HIV infection, because the concomitant spermicide use may increase risk of HIV acquisition or transmission.⁵⁸ Detailed information can be found in *Contraceptive Technology*.⁴¹

Fertility Awareness and Other Periodic Abstinence Methods

Periodic abstinence methods identify fertile days within each menstrual cycle, and the individual abstains during those fertile times. Fertile days can be determined using a menstrual calendar, basal body temperature, and cervical mucus consistency. In a recent national survey, 17% of adolescents report ever using periodic abstinence.⁶ Among both adults and adolescents, as many as 24% of individuals reporting periodic abstinence as their primary method of contraception will experience an unintended pregnancy within the first year of use. More concerning is the poor continuation rates for the method,²²⁰ even for individuals participating in clinical trials.²²¹ An additional challenge with adolescents is that ovulation may not be predictable in the first few year(s) after menarche. If periodic abstinence is used, counseling on dual use of a condom and more reliable alternative methods should be offered. More detailed information can be found in *Contraceptive Technology*.⁴¹

Withdrawal

Withdrawal, or coitus interruptus, is a method in which the male partner attempts to “pull out” his penis before ejaculation. Although typically considered a “nonmethod,” withdrawal is commonly practiced by both adults

and adolescents. In the National Survey of Family Growth 2006 to 2008, 8% to 11% of respondents reported using withdrawal at first sex,⁶ and in the 2006 to 2010 survey, 57% of adolescents reported ever using withdrawal as a contraceptive method.¹⁸⁸ Adolescents' reasons for using withdrawal include dissatisfaction with hormonal methods, and as a secondary or backup method to condoms or hormonal contraception.²²² Relationship development and the establishment of trust also were cited as reasons for use of withdrawal.²²² The typical-use failure rate of withdrawal across all age groups is 22%⁴³; however, unlike condoms, it provides no STI protection. Because of the common use of withdrawal, pediatricians should remember to ask about it; because of the limited effectiveness⁴³ and lack of STI protection afforded by withdrawal, pediatricians should encourage adolescents to adopt more effective hormonal and/or barrier methods.

SPECIAL POPULATIONS

Pediatricians care for adolescents with a range of medical conditions that can affect sexuality, sexual behavior, and contraceptive needs. The CDC has recently addressed the contraceptive needs of young women with medical conditions in its publication "US Medical Eligibility Criteria for Contraceptive Use."⁵⁸ Available online, this document summarizes the literature on safety and efficacy of different contraceptive methods by medical condition. Populations of particular importance to pediatricians are summarized as follows.

Adolescents With Disabilities

An estimated 16% to 25% of adolescents are identified as having special health care needs, including physical disability, developmental disability, and chronic illness.²²³ Sexuality and sexual health care needs in this population are often overlooked, yet data reveal

that adolescents with disabilities and chronic illnesses have similar levels of sexual behaviors and sexual health outcomes (eg, STIs).^{224,225} Adolescents with disabilities and chronic illnesses also have similar needs for counseling and support of healthy sexuality development.^{226,227} These data underscore the need for pediatricians to address sexuality and contraception as part of routine care and as a core function of a medical home, particularly for adolescents using teratogenic medications.

Adolescents with more severe physical disabilities or cognitive impairment may need hormonal contraceptives for menstrual control and hygiene. Adolescents with disabilities may have early or irregular menstrual cycles,²²⁸ and medications such as certain anticonvulsants and antipsychotics may influence the neuroendocrine system, leading to abnormal bleeding.²²⁹ Menstrual hygiene also may present a special problem for adolescents with motility and transfer difficulties, as well as for those with behavioral and developmental disabilities.²³⁰ Menstrual control and suppression is commonly achieved with COCs, transdermal patches, DMPA, and levonorgestrel IUDs.^{77,231,232} Continuous or extended cycles of COCs is a common approach,^{231,232} and there are reports of successful use of 52-mg levonorgestrel IUDs in adolescent patients.^{76,77,80} Surgical approaches (tubal ligation, endometrial ablation, or hysterectomy) are rarely necessary and present special ethical and legal issues. A detailed discussion of menstrual management for adolescents with disabilities can be found in recent review articles as well as professional consensus statements.^{231–233}

Adolescents With Obesity

Similar to adolescents with disabilities, sexuality and sexual health are often overlooked among adolescents with obesity. Although national

data demonstrate some weight and BMI-related variation in body image and sexual behaviors, the sexual behaviors and sexual health needs of adolescents with obesity are substantially similar to those of their normal-weight peers.^{234,235} Obesity and related endocrine effects may influence the efficacy and adverse effect profiles of contraceptives, including EC (see previous section on EC). Excess pregnancies were found among transdermal contraceptive patch users weighing more than 90 kg (198 lb; 0.9% vs 0.3% among "perfect" users).^{236,237} Data are limited and inconsistent about whether hormonal contraceptive effectiveness varies by body weight or BMI.⁵⁸ Systematic reviews and large cohort studies have revealed no or mixed effects for the effect of both body weight and BMI on COCs, IUDs, implants, and contraceptive injections.^{238–240} When examining complications, the World Health Organization and CDC found that among adult women, COC users with obesity are more likely than nonusers to experience thromboembolic complications.¹¹¹ However, the absolute risk of thromboembolic complications among adolescent COC users is low.

Women with obesity, either with or without polycystic ovary syndrome, are often anovulatory and experience infrequent menses. Metformin is frequently used in the treatment of these women and can increase the frequency of ovulation, increasing their contraceptive needs. A frequent concern by both adolescents and providers is additional weight gain with hormonal contraceptive use among adolescents with obesity. Adult data suggest that women with obesity are not more likely to have significant weight gain with combined or progestin-only contraceptives.^{241–243} In contrast, adolescents with obesity who used DMPA were more likely than normal-weight nonusers,

COC users with obesity, and normal-weight DMPA users to gain weight.⁹⁶

Increasing numbers of adolescents are having bariatric surgery performed, and these patients present special contraceptive needs. Presurgery data reveal a high prevalence of menstrual problems among adolescents with morbid obesity.⁸¹ Postsurgery data demonstrate an improvement in fertility, and professional consensus statements recommend delaying pregnancy for at least 12 to 18 months after bariatric surgery.²⁴⁴ Together, these suggest a need for highly effective contraceptives in such patients. The surgical procedures themselves may influence effectiveness of contraceptives. Postoperative complications, such as long-term diarrhea and/or vomiting, have the potential to decrease COC effectiveness.⁵⁸ Additionally, surgical procedures involving a malabsorptive component have the potential to decrease COC effectiveness.⁵⁸ Similar concerns about decreased COC effectiveness have not been described with laparoscopic placement of an adjustable gastric band. Given the challenges with oral, transdermal, and injectable contraceptives and the need for effective long-term postprocedure contraceptives, there is increasing use and success with levonorgestrel IUDs placed at the time of surgery.⁸¹

Adolescents With HIV

The vast majority of adolescents with HIV acquire their infection during adolescence through sex, intravenous drug use, or other behavioral mechanisms. Only a small proportion of adolescents with HIV are infected perinatally. National data reveal that sexual behaviors of HIV-infected adolescents do not differ substantially from their uninfected peers, and therefore, these adolescents have similar contraceptive and sexual health needs. However, because of risks of transmission to partners and because of drug interactions with antiretroviral

therapy (ART), adolescents with HIV infection present a challenge to prescribing contraception. Many antiretroviral agents have interactions with COCs, and a physician with expertise in HIV care should be consulted when prescribing hormonal contraception for an HIV-infected adolescent on ART.^{58,245} The CDC and the World Health Organization provide guidance on prescribing different contraceptives for patients with HIV infection receiving ART.²⁴⁶ Condoms are the preferred method of barrier contraception because of their demonstrated ability to decrease HIV transmission. Spermicides and diaphragms are contraindicated among HIV-positive women because of the potential for increased risk of genital lesions and potential increased risk of HIV transmission associated with nonoxynol-9. IUDs do not increase the risk of HIV acquisition or transmission and are safe and effective for HIV-infected individuals without increasing the risk of infections or complications in HIV-infected women. If COCs are used in HIV-infected adolescents receiving ART, a preparation containing ethinyl estradiol $\geq 30 \mu\text{g}$ should be prescribed.⁵⁸

Data on the interactions between ART and hormonal contraceptives (both combined and progestin only) are limited, but effects are known to include increased ART toxicity and, in the case of ritonavir-boosted protease inhibitors, decreased contraceptive steroid concentrations, potentially compromising contraceptive effectiveness. Other ART regimens (eg, zidovudine-containing regimens) are teratogenic, necessitating highly effective contraceptives.²⁴⁶

Adolescent Recipients of Solid Organ Transplantation

The improved survival of pediatric recipients of solid organ transplantation has prompted increased attention to

quality-of-life issues, including involvement in romantic and sexual relationships, issues that are typically addressed by the patient's pediatrician. Neither transplantation nor immunosuppressant medications decrease fertility, and conception can occur as early as 3 weeks after liver transplantation.^{247,248} Similar to other adolescents with chronic illnesses, transplant recipients are likely to be as sexually active as their peers.^{225,249–253} However, because these patients may underestimate their own fertility and because subspecialty physicians underestimate sexual activity and contraceptive needs in patients with chronic disease, it is imperative that primary care physicians assess these issues.^{254–256}

For transplant recipients who choose not to remain abstinent, a highly effective method is indicated. Patients who have established normal organ function and are stable at least 6 to 8 months after transplantation can use any of the currently available hormonal contraceptives, provided they do not have other contraindications to the estrogen component.^{58,254,257,258–260} Contraindications to estrogen, however, occur more commonly in transplant recipients. For example, COCs should not be prescribed to patients with active liver dysfunction or coronary artery disease.¹³⁹ Also, deterioration of organ function or episodes of rejection would require reevaluation and consideration of substituting a nonhormonal method, at least temporarily. Given the excess risks associated with unplanned pregnancies in transplant recipients, knowledge about the availability of EC is especially important.

Potential drug interactions should be assessed, both to avoid drug toxicities and to maintain the effectiveness of all prescribed medications.²⁶¹ For example, COCs can increase concentrations of immunosuppressive medications, such as cyclosporine, which has a narrow

therapeutic window and significant toxicities (see Table 7). Patient care decisions may require consultation with a clinical pharmacologist. To avoid monthly fluctuations in drug concentrations, patients using combined methods should use them continuously, without a hormone-free interval. Although 1 study suggests that immunosuppressant concentrations remain stable with use of the contraceptive vaginal ring,²⁵⁹ both the ring and the patch are sufficiently similar to COCs that, until further data are available, they should be used with the same precautions that apply to COCs. Drug interactions with progestin-only methods are uncommon; however, monitoring cyclosporine concentrations is advisable.²⁶²

Historically, IUDs have been considered contraindicated in immunosuppressed patients because of theoretical risks of both decreased efficacy and increased risk of infection. However, more recent evidence argues against these

theoretical risks,²⁶³ and the CDC does not consider IUDs contraindicated in patients with stable graft function.⁵⁸ Although data are currently limited, anecdotal experience with adult transplant recipients suggests the levonorgestrel IUD can be an excellent choice because of the lack of drug interactions and outstanding contraceptive effectiveness.

Adolescent Oncology and Other Medically Complex Patients

Pediatricians may be called on to provide contraceptives for patients with cancer and other complex medical illnesses. In addition to pregnancy prevention, these adolescents may need menstrual suppression for heavy menstrual bleeding, bleeding disorders, or chemotherapy. Other medical conditions, such as rheumatologic illnesses, may present issues related to estrogen use, thromboembolism, or medication interactions. For these and other complex illnesses, the principles

have been discussed in the previous sections, and consultation with appropriate adolescent medicine, adolescent gynecology, or family-planning specialists can be sought.

ADHERENCE AND FOLLOW-UP

Frequent follow-up is important to maximize adherence for all methods of contraception, to promote and reinforce healthy decision-making, and to screen periodically for risk-taking behaviors and STIs. Follow-up visits should include routine examinations, reassessment for contraception method, STI surveillance, and other sexual health preventive measures, such as human papillomavirus immunization. The timing and frequency of reassessment will vary depending on the contraceptive method and the patient's other health needs. An internal pelvic examination is not necessary for hormonal contraception (for a more complete discussion of

TABLE 7 Immunosuppressant Adverse Effects and Interactions With Hormonal Contraception

Type of Medication	Drug Interactions	Adverse Effects Influencing Contraception	Contraceptive Considerations
Corticosteroids (prednisone)	COCs may increase plasma concentrations of corticosteroids; monitor for increased corticosteroid effects	Hypertension Diabetes Weight gain, osteoporosis	Severe and uncontrolled hypertension is a contraindication to COC use. Low-dose pills have minimal impact on glucose metabolism. Monitor weight and BMD carefully if DMPA is used.
Azathioprine (Imuran ^a)		Liver toxicity	Liver dysfunction interferes with estrogen metabolism.
Mycophenolate mofetil (CellCept ^b)		Diarrhea, vomiting	Severe gastrointestinal disturbance could decrease COC absorption.
Cyclosporine, tacrolimus (Prograf, ^c FK506)	COCs may increase levels; monitor blood levels closely	Hypertension Hyperlipidemia Hyperkalemia Diabetes Headache	Severe hypertension is a contraindication to COC use. COCs have minimal effect on lipids. Drospirenone (a progestin with spironolactone-like activity) is contraindicated with hyperkalemia. Low-dose pills have minimal impact on glucose metabolism. Headache can be an adverse effect of steroid hormones: monitor headache frequency. ^d
Sirolimus (Rapamune ^e)	COCs may increase levels; monitor blood levels closely	Hyperlipidemia	COCs have minimal effect on lipids.

gynecologic examinations of adolescents in the pediatric office setting, see the 2010 AAP clinical report on gynecologic examinations for adolescents).¹¹⁷ Regularly scheduled visits need to occur to assess contraceptive issues, such as use, adherence, adverse effects, and complications. Adolescents should receive ongoing support and reinforcement by using motivational interviewing approaches to enhance effective and consistent contraceptive use, including engaging parental support for contraceptive adherence, when possible. In addition, condom use at each sexual intercourse must be advised and reinforced at every visit. Individual factors, relationship factors, family support, knowledge and

understanding of contraceptives, personal resources, access to confidential care, and fertility intentions have all been demonstrated to affect adolescent contraceptive choice. Adolescents rely on trusted health professionals, such as pediatricians, for accurate information, for individualized counseling and prescribing, and for support and problem-solving around continuation and adherence.

POLICY STATEMENT

Death of a Child in the Emergency Department

abstract

FREE

The American Academy of Pediatrics, American College of Emergency Physicians, and Emergency Nurses Association have collaborated to identify practices and principles to guide the care of children, families, and staff in the challenging and uncommon event of the death of a child in the emergency department in this policy statement and in an accompanying technical report. *Pediatrics* 2014;134:198–201

INTRODUCTION

The death of a child in the emergency department (ED) is an event with emotional, cultural, procedural, and legal challenges. The original policy statement, “Death of a Child in the Emergency Department: Joint Statement by the American Academy of Pediatrics and the American College of Emergency Physicians,” was first published in 2002.¹ It represented a groundbreaking collaboration between general and pediatric emergency practitioners regarding their professional obligations in managing the death of a child in the ED, recognized as one of the most difficult challenges in emergency care. This revised statement expands that collaboration to include emergency nursing and is issued jointly by the American Academy of Pediatrics (AAP), the American College of Emergency Physicians (ACEP), and the Emergency Nurses Association (ENA). The infrequency of child death in the ED and the enormity of the tragedy magnify the challenges in simultaneously providing clinical care, holistic support for families, and care of the team delivering care while attending to significant operational, legal, ethical, and spiritual issues. The evidence basis for these recommendations is detailed in the accompanying technical report of the same title.²

RECOMMENDATIONS

The AAP, ACEP, and ENA support the following principles:

- The ED health care team uses a patient-centered, family-focused, and team-oriented approach when a child dies in the ED.
- The ED health care team provides personal, compassionate, and individualized support to families while respecting social, spiritual, and cultural diversity.
- The ED health care team provides effective, timely, attentive, and sensitive palliative care to patients with life span-limiting conditions and anticipated death presenting to the ED for end-of-life care.
- The ED health care team clarifies with the family the child’s medical home and promptly notifies the child’s primary care provider and appropriate subspecialty providers of the death and, as appropriate,

coordinates with the medical home and primary care provider in follow-up of any postmortem examination.

- ED procedures provide a coordinated response to a child's death including the following:
 - Written protocols regarding
 - family member presence during and after attempted resuscitation;
 - preterm delivery resuscitation;
 - end-of-life care/anticipated death in the ED of a child with a life span-limiting condition;
 - collaboration with law enforcement staff to address forensic concerns while providing compassionate care;
 - institutional position on permitting the practice of procedures involving the newly deceased; and
 - best practice—outlining procedures after the death of a child (eg, a “death packet” with guidelines for completion of a death certificate, organ donation, etc)
 - Processes for notification of primary care and subspecialty providers and medical home of the impending death or death of their patient
 - Identification of resources, including other individuals and organizations, that can respond to the ED to assist staff and bereaved families, such as child life, chaplaincy, social work, behavioral health, hospice, or palliative care staff
 - Identification and notification of medical examiner/coroner regarding all deaths, as directed by applicable law
 - Routine offering of postmortem autopsy to families for all non-medical examiner-coroner cases
 - Clear processes for organ and tissue procurement
 - Identification and reporting of cases of suspected child maltreatment
 - Formal voluntary support and programs for ED staff and trainees, out-of-hospital providers, and others who are experiencing distress
 - Support of child death review activities to understand causes of preventable child death
- Emergency medicine, pediatric resident, and emergency nurse training includes specific education regarding the difficult issues raised by the death of a child in the ED, such as the following:
 - Evidence for supporting family presence during attempted resuscitation
 - Best palliative care practices for imminently dying pediatric patients
 - Communicating the news of the death of a child in the ED to parents and family
 - Best practice in discussion of organ donation or autopsy
 - Filing the report of suspected child abuse or neglect in the setting of a child death
 - Medical-legal issues and best practice surrounding completion of death certificates
 - Optimal documentation and collaboration with state and local child death review teams to identify strategies to prevent future child deaths
 - Self-care after difficult or troubling ED cases
- The ED health care team routinely considers care for the bereaved members of the patient's family that may include information and arrangements for bereavement care services, condolence cards,

and follow-up with family to address any concerns or questions.

The death of a child in the emergency department (ED) is one of the most challenging problems facing ED clinicians. This revised technical report and accompanying policy statement reaffirm principles of patient- and family-centered care. Recent literature is examined regarding family presence, termination of resuscitation, bereavement responsibilities of ED clinicians, support of child fatality review efforts, and other issues inherent in caring for the patient, family, and staff when a child dies in the ED. Appendices are provided that offer an approach to bereavement activities in the ED, carrying out forensic responsibilities while providing compassionate care, communicating the news of the death of a child in the acute setting, providing a closing ritual at the time of terminating resuscitation efforts, and managing the child with a terminal condition who presents near death in the ED. *Pediatrics* 2014;134:e313–e330

INTRODUCTION

When emergency clinicians are faced with an imminent child death in the emergency department (ED), they must carry out many complex tasks. They must treat a patient experiencing an acute and evolving medical situation, establish a compassionate relationship with family they have likely never met before, and support and work in team fashion with their colleagues as they acknowledge the human limitations to remedy a medical crisis. Many of the clinical, operational, legal, ethical, and spiritual layers to this complex care are discussed in this report and are listed in Table 1. The infrequency of these events and the magnitude of the tragedy combine to make the death of a child in the ED one of the most challenging problems facing emergency health care providers.

Despite the relative infrequency of these events, there is considerable diversity in the clinical presentation of the death of a child in the ED. In this technical report, child death in the ED is considered broadly, encompassing acute unanticipated trauma or illness, stillbirth or extreme preterm birth at the margin of viability, the child declared dead on arrival, the child who dies shortly after passing through the ED, and even the child with a known life span-limiting condition for whom the ED becomes the location of end-of-life care.

This technical report builds on the original technical report published in *Pediatrics* in 2005¹ in support of the 2002 joint statement of the American Academy of Pediatrics (AAP) and American College of Emergency Physicians (ACEP)² and a companion article published in *Annals of*

TABLE 1 Essential Components of Care in the ED When a Child Dies

Clinical
Resuscitation best practice
Termination of resuscitation
Identifying, validating, and respecting advanced care directives
Operational
Staff training in communication
Team response (including readily available support staff such as security, child life, chaplaincy, social work)
Family presence policy
Dealing with media ^a
Communication with medical home
Defusing/debriefing for team
Private location for family to be with deceased, means and location to conduct rituals
Legal and forensic
Organ donation
Autopsy
Working with police and coroner/medical examiner
Child protective services
Child fatality review team
Documentation in medical record
Preservation of evidence
Ethical
Resuscitation: how long is too long?
Prolongation of resuscitation efforts for family presence/organ donation
Practice on newly deceased
Initiation of resuscitation at the border of viability in extreme preterm birth
Spiritual and emotional
Needs of family, including saying goodbye, memory making
Needs of multidisciplinary team
Envisioning a “good death” in the ED
Follow-up care for family
Helping family to know everything was done
Assisting family in explaining to siblings, family, friends
Assisting family in locating community support to address grief and bereavement
Plan for postautopsy meeting to answer questions
Plan for scheduled follow-ups and marking of meaningful dates
Follow-up care for team
Scheduled voluntary defusing/debriefing with all members of the emergency care team who wish to participate

^a Not covered in this report.

Emergency Medicine in 2003.³ These earlier publications called for a patient- and family-centered and team-oriented approach to the provision of compassionate care while respecting social, spiritual, and cultural diversity. They outlined responsibilities of the ED staff

involved in the care of the child, including the responsibility to facilitate organ procurement and obtain consent for postmortem examinations; to facilitate the identification of medical examiner cases and the reporting of potential maltreatment cases; to assist team members, including emergency medical services (EMS) personnel, with managing critical incident stress; to notify the primary care provider and other clinicians/specialists; and to delineate the responsibility of follow-up of autopsy reports or other medical information. This revised report, as well as the accompanying revised policy statement of the same title,⁴ reaffirms those principles and examines recent literature regarding family presence during attempted resuscitation, recommendations regarding termination of resuscitation efforts, organ donation, benefit of autopsy, practicing procedures on the newly deceased, benefit of continued contact with surviving family members, and working to support state, local, and national child fatality review teams. New observations regarding the need for and the most effective ways to provide communication training, reflections on the effect of patient death on providers, and definitions of a “good death” are also reviewed. Additional existing resources from the emergency care literature are identified. Observations from venues outside the ED but with potential application to the ED setting are considered. Finally, a reconsideration of what can be called success in pediatric resuscitation is offered.

BACKGROUND

Data from the National Center for Health Statistics for the most recent year completed (2009) revealed that there were 73 million children younger than 18 years residing in the United States.⁵ Although the portion of the population younger than 18 years is

roughly 30% of the total population, fewer than 2% (48 000) of deaths occur in this age range. This statistic is strikingly different from a century ago, when 30% of all deaths were in children younger than 5 years. These data reflect progress in child health but also underscore that child death, unlike parental or spousal death, is no longer an expected part of life. In industrialized nations, child death stands out as a singular tragedy and an increasingly uncommon event in the professional lives of clinicians, even those whose practice is exclusively pediatric.

Beginning in 2006, the Health Care Cost and Utilization Project has provided a national database of ED visits with the Nationwide Emergency Department Sample.⁶ Fewer than 3% of all ED patient visits were children younger than 1 year; deaths in that age group accounted for 1.9% of all ED deaths. Patients 1 to 17 years of age accounted for 18% of all ED visits and another 2% of ED deaths. In total, the percentage of ED deaths among patients younger than 18 years is less than 4%, occurring less than 1 per 15 000 ED visits. Because of the relative infrequency of child death in the ED setting, few emergency clinicians have extensive experience with child death.

Beyond the relative infrequency of this event, there are other formidable challenges in managing pediatric deaths, including the following:

- deciding when to terminate resuscitative efforts;
- deciding when not to initiate resuscitative efforts;
- managing painful or distressing symptoms in pediatric patients;
- ascertaining family wishes or identifying existing advance directives;
- managing family presence in the setting of attempted pediatric resuscitation;

- communicating with and caring for the family;
- asking families in crisis about potential organ donation or autopsy (when, how, who asks);
- effectively discharging forensic responsibilities in a child death, especially when it may be the result of intentional injury or neglect, while attempting to respond to the family's loss with compassion;
- withdrawing or withholding no longer beneficial medical interventions for children with chronic life span-limiting conditions;
- balancing respect for the newly deceased and bereaved with the opportunity for needed practical experience for practitioners and trainees to enhance skills to prevent potentially avoidable deaths in the future;
- resuming work after the emotionally difficult episode, needing to "pick up and move on to the next case"; and
- addressing the personal and clinical team emotions of anger, sadness, inadequacy, or blame that often result after caring for a child who dies in the ED.

The health care team's perceived obligation to maintain a calm and proficient demeanor can be at odds with the empathetic behaviors that are valued as most helpful to families facing the loss of their child. Because ED providers are so often exposed to critical events, they may have evolved a protective mechanism that normalizes the abnormal events they see every day, what Truog et al⁷ have called the "routinization of disaster." And yet what parents, caregivers, and family members who are enmeshed in this uniquely catastrophic experience report as important and beneficial to them is the kindness, empathy, and genuine caring of their child's care

providers. Given that they can anticipate that death will be the most common outcome of cardiac arrest in a child,⁸ ED providers must add care of bereaved family members to their list of skills and responsibilities.

Lack of training in critical health care communication, particularly in the compassionate delivery of difficult news, is pervasive even today throughout the spectrum of health care education, including nursing education, medical school, and residency.⁹ A large national survey published in 2003 indicates that role models and faculty at the medical school level are not equipped to teach these skills.¹⁰ Nurses may also be ineffective in communication.¹¹ In a 2008 AAP statement reviewing communication skills,¹² it was noted that "health care communication is currently learned primarily through trial and error." There is increasing evidence that communication skills can and should be taught and learned,¹³ and there are a number of strategies specific to the practice of emergency care.¹⁴ Communication skills are now recognized as a required core competency in nursing, medical student, and resident training accreditation criteria.¹² Emergency clinicians should support explicit training and skill building in communicating the difficult news that they may be called to deliver when a child dies in the ED.^{15,16} Results of parent surveys confirm that the delivery of the news of their child's death is extremely important to the long-term well-being of family members. Skill and compassion in conveying bad news may be the most powerful therapeutic tool clinicians can offer affected families.¹⁷ An approach to notifying parents of the death of their child in the ED is provided in Appendix 1. As with other uncommon but critical events, simulations of management of the death of a child can be conducted by ED staff to prepare them for this rare event.

FAMILY PRESENCE

Family presence in the ED has been defined as "the presence of family in the patient care area, in a location that affords visual or physical contact with the patient during invasive procedures or resuscitation events."¹⁸ Initial resistance to allowing family presence during attempted resuscitation was based on fears of litigation and concerns that the emotional burden for family members of watching resuscitation would create situations that would distract ED personnel, potentially interfere with effective resuscitation efforts, and only add to a family's burden of grief. These fears have been systematically studied and for the most part clarified or eliminated.^{19–21} Mangurten et al²² reported that 95% of the families they surveyed would again wish to be present and felt that it had been helpful to them, and no disruption of care was documented. In a similar study examining pediatric trauma resuscitation efforts, there also was no difference in time to milestones of care in trauma patients with or without family members present.²³ Studies and position statements reflect the increasing ability of emergency clinicians to effectively support family presence during attempted resuscitation in the setting of effective staff preparation, appropriate policy development and implementation, and, when staffing allows, providing designated personnel to attend to family members.

Family presence has received widespread endorsement. Supportive articles have appeared in the ethics literature, the resuscitation literature, and the general and pediatric emergency medicine and nursing literature.^{18–27} The Emergency Nurses Association (ENA), AAP, and ACEP have position statements on family presence.^{24–26} The revised jointly issued policy statement from the AAP, ACEP, and ENA recommends that all EDs

caring for children have a written policy regarding family presence.⁴

As a further indication of the acceptance of family presence during resuscitation attempts, the debate has turned from a goal of family presence during resuscitation to the goal of family presence at time of death pronouncement.²⁷ Strict adherence to this goal may result in the prolongation of otherwise futile resuscitative efforts. An alternative to prolonging an otherwise futile resuscitation attempt when family have not yet arrived may be to designate a family surrogate, a staff member whose job is simply to be with the child. When family members do arrive after their child has died, they should be assured that their child was not alone at the time of death.

NONINITIATION AND TERMINATION OF RESUSCITATION ATTEMPTS

Deciding when to terminate resuscitation efforts or not to initiate them at all ranks among the most difficult tasks facing the emergency health care team caring for a critically ill or injured infant or child.^{28–30} Although these actions are frequently described as ethically indistinguishable, they may feel quite different in the moment of decision. Further complicating these decisions is a lack of objective data on which to base guidelines, a desire to allow for family presence, the hope to increase potential for organ donation, and provider distress with the tragedy of the death of a child, any of which may contribute to initiation of or persistence in likely futile resuscitation efforts. Differences between general and pediatric emergency physicians in time until termination of resuscitation efforts on a child were first described by Scribano et al,³¹ noting that pediatric-trained ED physicians reported being twice as likely to terminate efforts if there was no return of spontaneous circulation after 25 minutes. The authors speculated

that some of the observed differences between general and pediatric emergency physicians were more related to provider distress than to a lack of familiarity with guidelines.

Although improved clinical outcomes have been reported since instituting new Pediatric Advanced Life Support/American Heart Association guidelines for defibrillation and for chest compressions, a 2008 review of advances in pediatric resuscitation states that there is not sufficient evidence to base a recommendation for duration of resuscitation efforts in all situations.⁸ In particular, findings of better-than-anticipated survival from prolonged cardiopulmonary resuscitation (CPR) followed by extracorporeal membrane oxygenation initiated for children who experienced cardiac arrest in the PICU cannot easily be extrapolated to the ED setting.³² Criteria for termination of resuscitation are not discussed in the 2009 review article by Topjian et al,³³ and at this time there are no universal criteria for termination of resuscitation efforts in children. The 2010 Pediatric Advanced Life Support guidelines point out that clinical variables associated with survival include length of CPR, number of doses of epinephrine, age, witnessed versus unwitnessed cardiac arrest, and the first and subsequent rhythm. None of these associations, however, predict outcome. Witnessed collapse, bystander CPR, and a short interval from collapse to arrival of professionals improve the chances of a successful resuscitation.³⁴

Likewise, in the out-of-hospital setting, there are no nationally accepted guidelines for noninitiation of resuscitation or termination of resuscitation that apply to children. The National Association of EMS Physicians has criteria for adults who experience traumatic or nontraumatic cardiac arrest, but these guidelines explicitly were not applied to children. Even with adults, however, the decision to

make an on-scene pronouncement versus transport in settings of probable futility may be driven more by perceived family needs and provider comfort.³⁵ The little evidence that exists, however, speaks to the family benefit of stopping resuscitation; at least 2 studies in adult patients indicate that families may in fact adjust better after pronouncement on scene than with transport to a hospital.^{36,37} No such data exist for children in the United States, but a Swedish study in adolescents with sudden cardiac death is supportive of pronouncement on scene as an option on the basis of parental report.³⁸ However, Hall et al³⁹ noted that paramedics are far more uncomfortable with termination of efforts in the field for a child than for an adult. Therefore, a child or infant may be transported to the hospital even though the resuscitative efforts may be futile, in order to provide a setting with better resources for support of the family and providers.

The situation of unanticipated birth of an extremely preterm infant at the limit of viability presents yet another example of the dilemmas regarding initiation and termination of resuscitation efforts, made more complex by evolving criteria and conflicting opinions about outcomes for increasingly immature live-born fetuses.^{40,41} Although factors such as gender, antenatal steroids, and single or multiple birth all affect outcome, the factors most commonly used to assess viability and to predict outcome are birth weight and estimated gestational age; however, these “simple” data points may, in fact, be difficult to determine with any accuracy in the ED setting. When such information is available, many institutional practices reflect the policy described in Tyson et al,⁴² who suggested that infants born at 22 weeks’ gestation and less not be subjected to resuscitation efforts, that infants born at 24 weeks’ gestation or more should

all receive attempted resuscitation, and infants born at a gestational age between these ages should undergo attempted resuscitation only with parental agreement. The recommendation of parental agreement is consistent with the 2010 AAP/American Heart Association Guidelines for Cardiopulmonary Resuscitation and Emergency Cardiovascular Care for neonatal resuscitation,³⁴ which serves as the basis for the *Neonatal Resuscitation (NRP) Textbook, Sixth Edition*,⁴³ and which cautions interpretation within local policy but advises noninitiation of resuscitative efforts for infants born at a gestational age of less than 23 weeks, who are born weighing less than 400 g, or who have visible lethal anomalies, such as trisomy 13 or anencephaly. The Neonatal Resuscitation Program (NRP) guidelines further suggest that efforts be terminated if, after 10 minutes of effective resuscitative efforts, the infant has no spontaneous heartbeat.

In the absence of precise determination of gestational age and weight, the guidelines developed for antenatal counseling by Batton et al⁴⁴ may prove useful in the ED: namely, that if the clinical team believes that there is no chance of survival, resuscitation is not indicated and should not be initiated; if the team believes that a good outcome is very unlikely, then parents should be engaged in the decision-making process and their preferences should be respected; and if the team's assessment is that a good outcome is reasonably likely, resuscitation should be initiated and its benefit should be continually reassessed, in consultation with the parents. Alternatively, if neonatal specialists are readily available to the ED, resuscitation can be attempted until they can participate in the decision to continue. Comfort care should be provided for all infants, regardless of the goals of care; improved neurologic and physiologic outcomes from comfort

care are clear. Comfort care is of particular importance as well for infants for whom resuscitation is not initiated or is not successful as well as for their families; care provided at the end of life is remembered by the bereaved for the rest of their lives. Nursing care of the dying infant includes comfort care for the family. Nursing guidelines from other venues, such as the NICU, can provide tools for ensuring that families have the opportunity to create memories that will not only help them with their immediate pain but also comfort them for a lifetime.⁴⁵ These recommendations are in accord with the most recent NRP guidelines.⁴⁶ In any given ED, policy regarding initiation and termination of resuscitation attempts on the extremely preterm newborn infant should be developed in conjunction with perinatal subspecialists who are most knowledgeable about resources and outcomes in that region and in accordance with NRP recommendations.

REQUESTING ORGAN DONATION

Broaching the subject of organ donation after the death of a child in the ED can be an intimidating task. However, recent studies have indicated that families are more often appreciative than offended or overwhelmed by such requests when they are approached with sensitivity by skilled staff and with attention to the optimal timing.⁴⁷ US federal regulations require that the regional organ procurement organization (OPO) be contacted for all deaths and impending deaths so that their representatives can become involved in a timely manner.⁴⁸

The patient who dies in the ED often is not a candidate for solid organ donation but may still be a candidate for donation of tissue, including corneas, heart valves, skin, bone ligaments, and tendons. There is little published literature regarding tissue donation

requests when a cardiac death occurs.⁴⁹ Therefore, best practices for request of tissue donation have been extrapolated from the organ consent literature. Likewise, there is little information about best practices specific to donation of tissue or organs from a deceased child.^{50,51} Availability of suitable donors continues to be the major limiting factor for growth in organ transplantation, especially in pediatric recipients, because the size of the organs is a critical aspect of the match process. Although studies have shown that family members' decisions about organ donation are influenced by many factors, including whether the deceased's donation intentions are known, parents/caregivers of young children usually must make a donation decision without any direct knowledge about their child's wishes. Donation can be perceived by families and providers alike as a way to salvage some meaning from an acute, unanticipated, and tragic loss, although there is literature that calls that perception into question.^{52,53} Timely referral and the use of trained personnel in organ procurement is critical to ensure that a rushed approach regarding organ donation is avoided with the family. Although the process of organ procurement may start in the ED with the admission of a critically injured child, at present best practice suggests that conversations regarding solid organ donation not be initiated in the ED if a patient is going to be admitted to the hospital and that consent for donation is much more common when an OPO representative is able to assist the care team in presenting this option to the family. Consulting OPO staff while the child is in the ED may provide guidance for the best timing. When a child dies in the ED, any exploration of family wishes regarding tissue donation should follow at some time removed from the news of the child's death but optimally by an OPO staff member who has become familiar to the family during their brief

stay. Ideally, supportive staff, such as a social worker, chaplain, and/or child life specialist, should be present during any request.⁵⁴

AUTOPSY

Autopsy requirements and standards vary by state. Emergency care providers should be aware of the laws that govern postmortem practice in their state and provide information to the family accordingly. The medical examiner or coroner should be notified, because the majority of ED deaths in most states will be under his or her jurisdiction. Hospitals may establish policies and procedures in collaboration with the medical examiner's or coroner's office for handling bodies after death in the ED. In the event that the medical examiner or coroner declines autopsy, the ED physician may recommend autopsy and consult the hospital pathologist. Autopsy is generally valued for its ability to provide additional diagnostic and epidemiologic data; however, Feinstein et al⁵⁵ argued for a family-centered analysis of benefits derived from autopsy. They noted that autopsies also yield information that may inform parents' or siblings' subsequent reproductive or other health choices or other information pertinent about the deceased child, may assist with quality assurance and improvement, and may provide general knowledge that benefits both families and the clinical care teams. Framed in this fashion, parents may be grateful for the request. Emergency clinicians who understand these additional potential benefits of autopsy for families may be more comfortable in discussing it with them.

Medical Documentation and Notification of the Child's Medical Team

It is the responsibility of the emergency health care team to ensure prompt notification of the primary care pro-

vider, child's medical home, and other appropriate members of the child's medical team, including out-of-hospital providers, in the event of a child's impending death or death in the ED. Families expect that their primary care provider will be aware of their child's death, and the task of notifying the medical home and others of a child's team should not fall to the family. Their loss may be further compounded if they do not hear from their child's providers or there is no outreach or acknowledgment from those who have cared for the child over time. If the child's medical team is not aware, for instance, routine reminders for well-child visits or immunizations might continue. If the child had subspecialty providers, the same guidelines may hold true; and in some conditions and cases, the connection between subspecialist and family may be stronger than that between family and medical home.

In addition, such communication is beneficial for the ED team, to provide helpful background information and to know that bereaved families will be followed by caregivers who have known them before the child's death. The medical home may supply the ideal staff to provide a presence at memorial services, sibling support, and follow-up review of any autopsy findings. Routine follow-up meetings happen infrequently for families of children who die in the ICU setting,⁵⁶ and the frequency of routine follow-up meetings with ED staff is unknown. Autopsy review has benefits not only for the family but also for medical personnel as well, and further information is needed about the impact for families and health care team members on providing this practice.

The development of a policy and procedure for handling of the body may include the following:

- a death packet and checklist to ensure that all appropriate notifications are accomplished;
- documentation of release of valuables;
- documentation of release of the body;
- notification of a funeral home;
- completion of the death certificate in accordance with state law, as applicable; and
- notification of the child's primary care provider.

SUPPORTING THE WORK OF CHILD FATALITY REVIEW TEAMS

Death review is a potent tool for understanding and preventing avoidable deaths. Although child fatality review teams (CFRTs) were first established to review suspicious child deaths involving abuse or neglect, CFRTs have expanded toward a public health model of prevention of child fatality through systematic review of child deaths from birth through adolescence. Child fatality review is supported at the federal level by the National Center for Child Death Review, funded by the Maternal and Child Health Bureau since 2002; by 2005, all but 1 state reported providing state or local review of child deaths. In 2009, 27 states were contributing to the national database maintained by the National Center for Child Death Review.⁵⁷

Child fatality review operates on the principles that a child's death is a sentinel event, the review of which can lead to an understanding of risk factors when based on a multidisciplinary and comprehensive review. Emergency clinicians can support this mission at several levels: by notification of their local or state team when a child death occurs; by advocating for access to ED records regarding the case when legislation, regulations,

and policies allow the confidential exchange of information; and by active participation of ED staff on a particular review or as standing members of the review team. Because most ED deaths will be medical examiner/coroner cases, notification of the CFRT will usually be ensured by that mechanism.

The National Center for Child Death Review recommends that local and state CFRT boards include an ED clinician as a standing board member.⁵⁸ When invited to attend a specific case review meeting, emergency clinicians should make every effort to attend, share information on a specific case and/or general information on ED practices and policies, and encourage improvements in systems and prevention. Emergency clinicians are important to CFRTs, because they can supply information on services provided to a particular child or family if seen in the ED as well as general information related to emergency care, including types of injuries and deaths, medical terminology, and concepts and practices specific to emergency care. They can further support team activities by providing the medical information needed for successful prevention campaigns and strategies. Simply documenting, in detail, the circumstances of a child's death allows the emergency clinician to play a powerful role in the prevention of disease and injury. Emergency health care providers should support training in optimal collaboration with CFRTs and in the documentation of circumstances of death, the completion of death certificates, and analysis of findings on physical examination that may shed light on the cause. The use of CFRT data may result in changes to child welfare systems, improvement in training and interagency protocols, and new legislation and regulations. The determination of the leading causes of preventable deaths has resulted in

implementation of prevention procedures (eg, child safety restraints and pool fencing) and prompt public policy discussion and action.

BALANCING FORENSIC RESPONSIBILITIES WITH COMPASSIONATE CARE

In 2009, an estimated 1770 children in the United States died as a result of inflicted injury or neglect. Nearly half of fatal child maltreatment cases occur in infants younger than 1 year, and 80% occur in children younger than 4 years. Any child death presenting to the ED may require consideration of maltreatment as a cause of death, especially when the history does not match the clinical presentation.⁵⁹ Although there is literature to support the need for training and resources for the responsible performance of forensic duties in the ED in situations involving the death of a child,^{60,61} there is little reported that describes the tension between health care providers and law enforcement that can sometimes result when the death is suspected to be the result of neglect or homicide. The emergency clinician is called to balance the needs for accurate forensic information with the compassionate care of the family whose child just died. In the focus on time-sensitive, potentially lifesaving interventions, medical staff may inadvertently destroy crucial evidence, creating the potential for conflict with law enforcement officials. In the acute care setting, it is often impossible to determine whether a potentially lethal condition has resulted from intentional or accidental causes, and the bereaved family should be offered access to their child, in accordance with local policy, while making every effort not to compromise patient and staff safety or evidence. Access to a forensic nurse examiner, who may have developed collaborative working

relationships with law enforcement professionals, may be beneficial.⁶² Forensic nurse examiners have been specially trained in evidence collection and the care of victims and secondary survivors and may provide another option for standardized expert care. They can be notified of a pending arrival of a pediatric patient in extremis, remain exempt from the actual resuscitative care, and provide an additional trained team member whose primary purpose is the preservation of evidence. Appendix 2 of this report offers a sample protocol for collaboration between health care providers and law enforcement in situations in which there is concern for intentional injury resulting in death.

PRACTICE ON THE NEWLY DECEASED

Studies from the previous decade have suggested that 47% to 63% of emergency medical training programs allowed the practice of procedures on the newly deceased to ensure the development and maintenance of skills for trainees and clinicians to benefit future patients; however, in the past, consent was rarely sought.⁶³ With the increasing frequency of family presence during resuscitative efforts, evolving sophistication of alternative methods of training such as simulation, and a growing sense among participants or observers that norms of decency are being breached, this practice is likely to be diminishing in frequency. Interestingly, consent for procedures on the newly deceased is sought and obtained more often in the NICU than in the ED, possibly because of the existence of a longer standing relationship and trust. The Society for Academic Emergency Medicine has taken the position that all emergency medicine training programs should develop a policy regarding practice on the newly deceased and make that

policy available to the institution, educators, trainees, and the public.⁶⁴ The ENA has issued a policy statement affirming the legitimate need to master critical and lifesaving procedures, to obtain consent, and to consider alternative teaching methods such as simulation.⁶⁵

FAMILY BEREAVEMENT

The *Emergency Department Bereavement Resource* manual from the National Association of Social Workers is a practical resource for optimal ED preparation for the death of a child in the ED.⁶⁶ The manual also offers practical suggestions for memory making and bereavement care in the ED after a child has died. Most families not present at the time of death felt that they should have received the news from an attending physician. Similarly, most felt that a follow-up call from providers who were present with them during and after the time of their child's death would be meaningful, although few reported receiving such a call.⁶⁷ Postmortem follow-up communication has been shown to be perceived as very positive by survivors of adult patients who died in an ED¹² and for bereaved parents of children who died in the PICU.⁶⁸ Parents recognize staff with whom they have had only this brief intense encounter as the last people to see their child alive, with whom they shared an overwhelmingly difficult event in their own lives, and therefore as important keepers of the memory of their child. It can be comforting to ED staff, who themselves mourn the death of child patients, to know that even small gestures of condolence such as a card or phone call can have a profound and positive effect on grieving families. A sample bereavement checklist for use in the ED is included in the Appendix 3 of this report.

Parents reported that they valued the care provided by physicians and other members of the emergency care team who were accessible, honest, caring, and able to speak in lay language at a pace that matched the parents' ability to process and comprehend. The pace of this information is necessarily accelerated in the emergency setting, but the family's need for continued access to providers, whether from the ED staff or from more familiar resources, is very likely the same. It is the responsibility of ED clinicians to ensure that families will receive follow-up from the most appropriate source for that family, which may indeed be the ED staff in some cases.

COLLABORATION WITH PEDIATRIC PALLIATIVE CARE SERVICES

Studies in children with known life span-limiting conditions report that between 3% and 20% of deaths in that population will occur in the ED.^{69,70} Because the ED remains part of the safety net of care for many children who are dying at home or who face a known life span-limiting condition, it is therefore sometimes the unanticipated venue for end-of-life care for such children. Increasingly, children with life span-limiting conditions may be cared for by local agencies and clinicians providing pediatric palliative care. Palliative care is a growing subspecialty within pediatrics, as evidenced by the recent creation of a Section on Hospice and Palliative Medicine within the AAP and recognition of the specialty of palliative care through a certificate of added qualification by the American Board of Pediatrics and other American Board of Medical Specialties boards. Palliative care services are not uniformly available, however, even at tertiary care or exclusively pediatric facilities. Nevertheless, as more

children are provided palliative care services, explicit and anticipatory collaboration between pediatric palliative care services and their corresponding EDs will likely improve care for such children. Many children receiving palliative care have had the opportunity to develop advance care plans. It can be very helpful for ED staff to have an understanding, in advance, of the hopes, concerns, and wishes that the child and family may have expressed. The emergency information form template developed by the Emergency Medical Services for Children program, in conjunction with the AAP and ACEP,⁷¹ includes advance directives that can be helpful in critical decision making with the family. Pediatric palliative care specialists can help families by anticipating which ED and EMS services will serve as entry points for their children and by sharing relevant medical history and care plan information with the EMS and ED personnel, with permission of the family. Similarly, when ED clinicians identify a child who might benefit from such a care plan, they may consider contacting pediatric palliative care resources to help develop such a plan for future potential ED visits. Pediatric palliative care teams can be a helpful resource for providing or identifying bereavement follow-up resources for individual families, for assisting to develop a consistent policy for bereavement follow-up from the ED, and for supporting ED caregiver gatherings and debriefings after the death of a child. An innovative project to integrate palliative care principles into emergency medicine practice provides additional resources on the Web site of the Center to Advance Palliative Care (www.capc.org). A guideline for developing a protocol for planned death in the ED of a child with a known terminal condition is included in Appendix 4.

THE CONCEPT OF A GOOD DEATH

The idea of a “good death” is a concept rarely discussed in the emergency medicine literature, and it is difficult to apply paradigms developed outside of the ED, mainly in the realm of adult palliative care, to the acute, unanticipated death of a child in the ED. The Institute of Medicine report on childhood death provides the following definitions for good and bad deaths:

“A decent or good death is one that is: free from avoidable distress and suffering for patients, families, and caregivers; in general accord with patients’ and families’ wishes; and reasonably consistent with clinical, cultural, and ethical standards. A bad death, in turn, is characterized by needless suffering, dishonoring of patient or family wishes or values, and a sense among participants or observers that norms of decency have been offended.”⁷²

Modern medicine has cultivated an unspoken belief that death is a failure on the part of the medical system, and the culture of the ED is perhaps most particularly vulnerable to this covert belief. A first step toward developing an understanding of what a “good death” might be in the ED setting is necessarily the acknowledgment that death is not avoidable. The knowledge and application of best resuscitation practices, whether in terms of applying interventions or appropriately withholding them, are required to know that a death was unavoidable. A second aspect of what might constitute a “good death” in the ED is caring for the survivors of the child’s death in a way that affirms their trust, allowing them to understand the events leading up to death, to exert some control in the situation, and to say goodbye to their child in whatever way is meaningful to them. These tasks have been identified as critical to the well-being of a bereaved family and can be supported by the clinical team with practical assistance, information, and compassion.^{73,74}

CARE FOR THE CARE PROVIDER

Finally, how ED staff care for each other as members of an interdisciplinary team of care providers is a third essential aspect of a “good death.” All ED staff benefit from training in communicating bad news, in managing the families’ expected emotional responses, and in understanding and managing the emotional responses in ourselves and our colleagues. It is important to offer voluntary defusing or debriefing to staff after critical incidents, such as the death of a child, although it is often challenging to find a time to gather those who wish to participate. However, Treadway’s⁷⁵ compelling essay, “the Code,” suggests that even a simple acknowledgment at the bedside after the death of a patient may be beneficial to staff. She speculates that there may be a healing potential to closing rituals that are communal rather than private. An example of a brief closing ritual is provided in Appendix 5 of this technical report.

SUMMARY

The death of a child in the ED remains one of the greatest challenges for ED staff. Since the original technical report,² the science of resuscitation has advanced and national organizations have strengthened position papers to facilitate family-centered care, including family presence during resuscitation. Concepts of the medical home, child fatality review, and pediatric palliative care have evolved. Hospitals can adopt policies and practices that provide guidelines for the care of the patient, family members, and care providers. These policies should incorporate family presence, termination of resuscitation efforts, bereavement protocols, and evidence preservation. It is important to address compliance with laws governing jurisdiction after death and the means to support staff when a child dies in the ED.

APPENDIX 1: GUIDELINES WHEN NOTIFYING A FAMILY OF THE DEATH OF THEIR CHILD IN THE ED

Modern medicine has cultivated an unspoken belief that death is a failure on the part of the medical system, and the culture of the ED is perhaps most particularly vulnerable to this covert belief. It is helpful to acknowledge that death is not avoidable in many of the conditions we are called on to treat in the ED. When it feels as if all you have left is the terrible news of a child's death, in fact your presence, empathy, practical assistance, and information enable you to provide a bereaved family with essential assistance that they will need to adjust to their loss. Families who lose a child through an acute and unanticipated event have at least these tasks to address: they need to understand the events leading up to death, to feel that they can exert some control over a universe suddenly completely out of control, to be able to say goodbye to their child in some meaningful way, to be able to make sense of the death, and to be able somehow to carry the child forward in their lives as they negotiate a new and ongoing relationship with the child they have lost. Your role in telling the family about the death of their child can help them toward accomplishing these tasks.

Preparation

First, take a moment for self-reflection, to acknowledge your own feelings (inadequacy, guilt, sadness, anger, fear) and perhaps to find a colleague with whom to share those emotions beforehand. Take note of those emotions, whatever they are, and then, without comment or criticism, allow yourself to put them aside.

Think for a moment how you might act if a dear friend told you that he or she had just received terrible news: what would you do, as one human

being to another? Use that as a model of how best to help this family with the news you have to give them. Strive to be a kind and steadying presence.

Families take it as a mark of respect and an indication of how importantly we view their loved one when the responsible attending physician is the one notifying the family.

Know and use the child's name.

Ensure that the right family members have been gathered and available resources have been assembled (which might include chaplaincy, social work, child life, or outside family supports, such as family chaplain or primary care provider).

Use a skilled medical interpreter, not a family member, for any translation needs. If using a family member is the only recourse, acknowledge to the family interpreter how difficult it is to hear bad news and then have to share that news.

Choose an appropriate setting that is quiet, provides privacy, and has enough places to sit for all who are needed to be present, with water and tissues available. Make yourself available and presentable (turn off beeper, check appearance, be sure to sit down).

Have a written copy of your name and contact information available. You may want to include other staff member names as well, such as the primary nurse, the social worker, child life, etc.

Steps in the Process

Introduce yourself and your role, shake hands or touch family members if appropriate, sit down at eye level.

If appropriate, determine what the patient and family understand about the present situation. "Please tell me what you already know about what has happened to [child's name]."

Prepare them with fair warning: "I am so sorry that I have to give you this bad news." Hold them in your gaze.

Continue to hold them in your gaze and inform them of the death in a direct manner, using the words "die" or "death." For example, "We did everything we possibly could, but [child's name] has died."

Sit quietly and allow the family to respond. The entire range of human emotion is possible at this moment. Resist the temptation to fill this silence and allow the family to be the first to break the silence.

Hear and respond to the family and patient's emotions, and provide additional information at the family's or patient's pace. (Avoid statements that begin with "I know you must be feeling very....") Instead, acknowledge what you see or feel. "I cannot imagine how difficult it must be to hear this news."

Solicit questions, assess understanding, and follow the family's lead. "I have given you such terrible news. Would it help to see [child's name] now, or do you have any questions for me, anything that I can explain better?"

Families may not ask but may be comforted to know that their child did not suffer, so if it is possible to give that reassurance, do so.

Any bad outcome with a child is inextricably linked to parental feelings of guilt. If it is possible to give reassurance about the family role in the event or note any contribution they made that was helpful, do so. "I don't see any way this accident could have been anticipated." Or, "Your information about her medical problems in the past was essential information for us."

Be prepared to repeat information, because it is nearly impossible to take in new information when under the kind of stress that a family member would be feeling at this time. Nevertheless, understanding and sometimes even reconstructing the events that led up to their child's death are often an

essential part of family acceptance and well-being after the loss of a child. Even simple information about what will happen next or what choices they have will be helpful. Your ability to give the information they need and ask for, at the pace they require, can be one of the most therapeutic “procedures” you can perform.

Offer assistance in helping the family to share this news with others, such as siblings or young children. Let them know that you will be notifying the child’s primary care provider and any relevant specialists.

Give your contact information in written form and let the family know of any follow-up arrangements, such as a call from the ED social worker in the next day or so.

Consider writing a condolence note to any family to whom you have had to give the news of their child’s death in the ED. It is an act with remarkable potential for healing.

APPENDIX 2: SAMPLE PROTOCOL FOR COLLABORATIVE PRACTICE WITH HOMICIDE INVESTIGATION ON SITE IN ED

City Police Department Homicide Division

The following procedures are to be used by city police officers when responding to a death involving a child

age ≤ 6 years at an area hospital. The procedures are designed to maintain the integrity of the police death investigation while permitting the hospital staff the continued use and management of the ED. The procedures also recognize the rights of the family to have access to their child to grieve the loss. Compassion and cooperation are key in handling these situations, and officers should always exercise good judgment in their decisions as it relates to child death investigations. If there are any questions concerning these procedures, please contact your city’s Homicide Division for resolution and guidance. A sample algorithm is provided in Appendix 2A.

Child Death Investigation Procedures

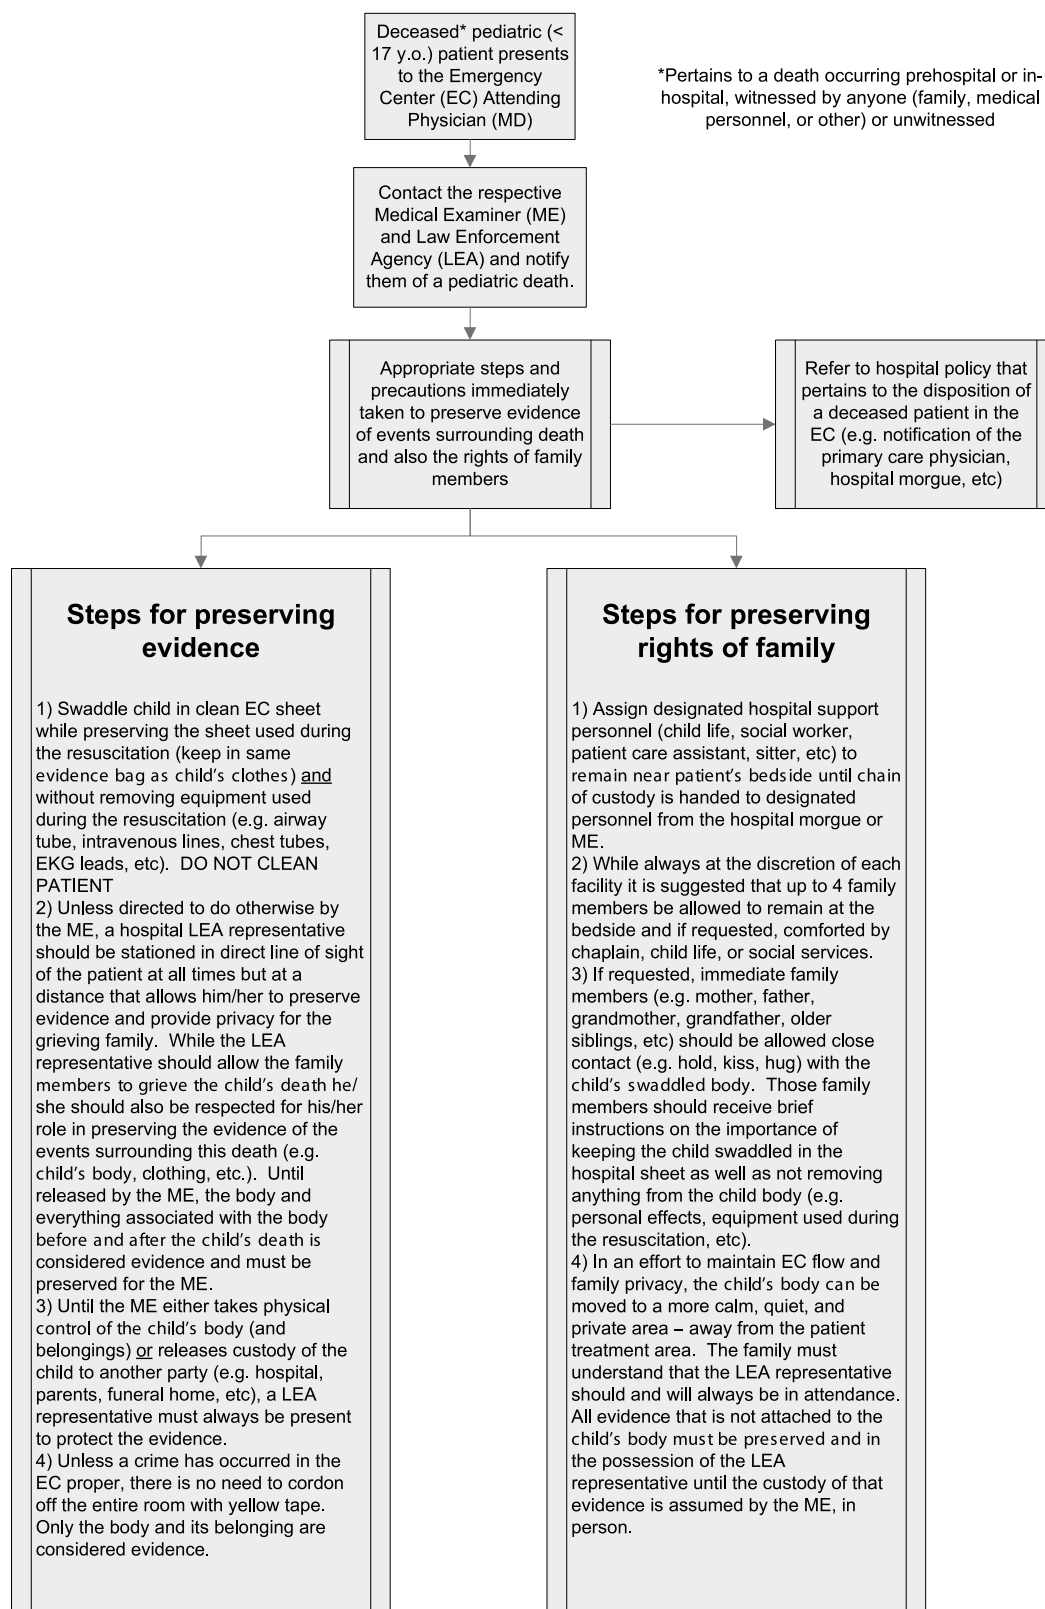

- When notified of a child death at a local hospital, responding officers, whether on-duty or working security, will ensure that the Homicide Division is notified immediately of the death. As many details as possible of the death should be obtained and relayed to the Homicide Division, such as name of the child, location the child was transported from, who transported the child, and any medical history or condition known.
- If the child was transported to the hospital from an outside location, make sure an on-duty unit is dispatched to the location to secure the scene as part of the investigation. In most instances, on-duty units will already be involved. If not, the Homicide Division desk officer can assist in getting a unit sent to the transporting location.
- Allow hospital staff to move the child out of the ED treatment room to another room or morgue. The officer will stay with the child and “observe and record all observations” until the arrival of the homicide

investigators. Remember, the ED room IS NOT a crime scene; the evidence for the investigation is the body of the deceased.

- Immediate family members should be allowed access to grieve the loss of their child. The officers should remain with the child and the family members until the arrival of the homicide investigators. Hospital staff should swaddle the child’s body in a clean sheet while preserving the sheet used during resuscitation efforts and without removing equipment used during the resuscitation efforts.
- If there are “obvious” signs of trauma, such as broken bones, significant bruising, or other injury indicating foul play in the child’s death, the child’s body may be removed from the ED treatment room into a secure room or morgue pending the arrival of homicide investigators. In this instance, there should be no contact with family members and the child’s body should be secured as evidence. Any questions about this should be directed to the Homicide Division.

In cases of child deaths in which the child has a history of medical problems and treatment of a long-term illness that make it clear that the death does not involve foul play or negligence, homicide investigators may elect not to respond or conduct the investigation. In those instances, the officer is responsible for preparing the report and conducting the scene investigation. This decision is made by the Homicide Division duty lieutenant, and all decisions about the homicide response should be directed to him or her.

Any questions about the handling of child death investigative procedures at area hospitals should be directed to the City Police Homicide Division.

APPENDIX 2A

The deceased patient in the emergency center (EC) decision tree: balancing the rights of survivors with the necessary preservation of evidence (courtesy Paul Sirbaugh, MD, personal communication). EKG, electrocardiogram.

APPENDIX 3: SAMPLE RESOURCE GUIDE FOR ED BEREAVEMENT CHECKLIST AND MEMORY BOX

This resource is meant to help guide you in the next stage of your care for a bereaved family.

Your interventions and caring have the potential to bring much comfort and meaning to this family and significantly influence their grieving.

Sections I and II: Demographics/Information

Please complete the Bereavement Checklist, which will help with bereavement follow-up and staff support. Please place the finished checklist *in the designated location/or to the designated personnel*.

Section III: Family Members

Our ED offers the option of family presence during invasive procedures and resuscitation. A family facilitator, nurse, social worker, or physician should assess the family before being with the patient. The family facilitator should accompany the family to provide support and medical explanations.

For many families, this may be their first experience of death, and they will not know what is permissible or expected. They may not know what will be comforting or healing to them now or in the future and will look to us for guidance. You might say something like “Many families have told us that they were comforted by the memory of talking to the patient or holding or touching their loved one—would you like to be able to do that?” Whenever possible, it is desirable to offer family private time (accompanied or unaccompanied as they request) to be with their loved one after death.

Family members may arrive after the child’s body has been transported to the morgue and the morgue staff are not available. If appropriate, the resource nurse should notify the nursing

supervisor and police and security to bring the family to the morgue and identify supportive staff (social work, nursing, physician) to accompany family members.

Section IV: Memory Box

The memory box is a legacy gift that can be given to family members after the death of their child. It can include hand and foot molds made out of model magic clay, handprints and footprints using inkless wipes and paper, a lock of hair, photographs if the family so chooses, and any mementos the child came with (clothes, shoes, jewelry, hospital band, hair accessories, etc). The directions for making the clay imprints and inkless prints are in each bereavement box, along with the necessary tools to make them. All of the memory box supplies (including resources and blankets) are kept _____. Sometimes families (including siblings) like to be involved in making the ink prints and clay imprints, so this opportunity should be offered to the family. More than 1 box can be made for families if the parents/caregivers live separately. Extra copies of the ink prints can be made using the copier for additional family members. If the family does not want to take the box home with them at this time, please let them know it will be kept at the hospital in case they change their mind over the next several months. Please lock the box in the valuables cabinet if the family does not want to take it home at this time.

Section V

Notification

Most ED deaths are considered a mandatory autopsy by the medical examiner. If the medical examiner decides to accept the case while the family is still in the ED, the family should be told, because it can affect funeral arrangements. Please note that the OPO will automatically be notified by

the hospital when the death certificate is completed. Studies have shown that professional OPO staff members are more skilled (even more than seasoned ED staff) at discussing potential organ donation with families, so you should defer all discussion of organ donation to OPO staff. In pediatric deaths of uncertain etiology, such as suspected sudden unexpected infant death or abuse, it is sometimes helpful to arrange with the medical examiner that the autopsy be performed at a facility with specific pediatric expertise.

Aftercare of the Deceased

To the extent possible, we should respect and support faith-based or cultural traditions around treatment of the deceased after death. For instance, for some traditions, it is not acceptable to leave a deceased person unattended, whereas for others it may not be acceptable for the child’s body to be handled by someone of the opposite sex. You might ask “Does your family culture or faith tradition give you guidance about what should happen after someone dies? We would like to support you in that if we can.” For many families, particularly those dealing with the loss of a child, the thought of leaving the deceased child alone in the morgue is very difficult. If a medical examiner autopsy is declined, it is sometimes possible to arrange for the funeral home to pick up the child’s body from the ED. This procedure involves the family identifying funeral home, attending physician completing a death certificate, and admitting staff processing the paperwork.

APPENDIX 4: GUIDELINES FOR DEVELOPING A PROTOCOL WHEN THE ED BECOMES THE UNANTICIPATED VENUE FOR END-OF-LIFE CARE FOR A CHILD WITH A TERMINAL CONDITION

Although the ED is not a common venue for end-of-life care of children with

***Please place this finished checklist _____.

APPENDIX 3A

Bereavement Checklist. MR, medical record.

known terminal conditions, as many as 10% of children with complex medical conditions will die in the ED setting. Some of those children will have advance care plans and family may have hoped that their child could die at home. However, in many locales, there are not resources to provide hospice or end-of-life care in the home setting for children, and many parents/caregivers report that even when the child's death is anticipated, the presence of medical personnel at the time of active dying is critical to their support and comfort.

In developing individual institutional guidelines for the care of a child with a terminal condition who presents to the ED actively dying, consider input from the following stakeholders if available:

ED physician, nursing and administrative staff
Hospital palliative care
Chaplaincy
Social services
Child life services
Pharmacy (for rapid access to pharmacologic management of symptoms)
Admitting staff
Case management
Hospitalist service (for consideration of rapid/direct admission or transfer to an alternate site)
Community-based palliative care providers

Consideration should be given to clarification of the means to facilitate the following:

- Assessment of the family's wishes, including resources needed for the child to return home to die

- Expeditious symptom management (respiratory distress, delirium, seizures, pain, control of secretions, control of bleeding)
- Provision of a private space in the ED, with the option for family to hold child if feasible and desired
- Contacting all existing care providers on the child's team
- Identification of alternate venues of care, including inpatient service, residential hospice, home
- Memory making by family members
- Ensuring bereavement follow-up, whether by ED staff or other
- Ensuring debriefing mechanism for ED and EMS staff.

In the event that a child with an advance care plan presents to the ED in medical crisis:

- Provide all comfort measures.
- Acknowledge all family members present
- Ask about current goals of care (eg, maximizing comfort versus attempting to prolong life)
- Engage in rapid resolution of severe distress and manage ongoing symptoms such as pain, secretions, seizures, delirium, respiratory distress, bleeding
- Provide private location as possible, with option for family to hold child if feasible and desired
- Ask family regarding their wishes at this time.
- For example: "We will keep [your child] safe and comfortable. If this

is her time to die, what can we do to support you and your family best? Is there anyone (physician, faith community, family, etc) you would like us to contact?"

- Contact primary and specialty care providers
- Notify OPO if indicated
- Assess optimal venue for care if death is not imminent: for example, "If your hope would be that your child could be at home when he/she dies, what resources will you need for your child to be safe and comfortable there? If we cannot secure those in your home setting, we will try to find the best place for you to be as a family. Would you like us to arrange for your child to be admitted to the pediatric floor/residential hospice?"
- Provide opportunity for memory making, any rituals to support faith-tradition or cultural practice, and family leave-taking
- Identify ED and EMS staff involved in care for participation in staff debriefing and in any bereavement follow-up for family.

APPENDIX 5: EXAMPLE OF A CLOSING RITUAL AFTER THE DEATH OF A CHILD IN THE ED

"I thank everyone here for their efforts to save [this child's name] life. Please take a moment in silence with me now to acknowledge our sorrow at his or her passing... In his or her name [touching the child if appropriate] may we each be rededicated to our work."

POLICY STATEMENT

Emergency Contraception: Addendum

FREE

COMMITTEE ON ADOLESCENCE

This is an addendum to the American Academy of Pediatrics Policy Statement “Emergency Contraception” (*Pediatrics* 2012;130(6): 1174–1182).

In April 2013, Judge Edward Korman of the US District Court of Eastern New York directed the Food and Drug Administration (FDA) to lift the ban on over-the-counter availability of levonorgestrel-based emergency contraceptives without a prescription and without point-of-sale or age restrictions. In June 2013, the Obama administration withdrew its appeal to the Korman ruling, and the FDA allowed the 1-pill formulation Plan B One-Step (Teva Women’s Health Inc, Frazer, PA) to be made available on the shelf without age restriction in the United States. The FDA granted Plan B One-Step 3 years of exclusive rights to sell the product without an age restriction. One-pill generic versions will likely be allowed to be sold on the shelf next to Plan B One-Step, but these products will require age verification and will not be sold to those younger than 17 years without a prescription. The 2-pill formulations of levonorgestrel-based emergency contraceptives will remain behind the pharmacy counter and will also not be sold to those younger than 17 years without a prescription.

Fractures are common injuries caused by child abuse. Although the consequences of failing to diagnose an abusive injury in a child can be grave, incorrectly diagnosing child abuse in a child whose fractures have another etiology can be distressing for a family. The aim of this report is to review recent advances in the understanding of fracture specificity, the mechanism of fractures, and other medical diseases that predispose to fractures in infants and children. This clinical report will aid physicians in developing an evidence-based differential diagnosis and performing the appropriate evaluation when assessing a child with fractures. *Pediatrics* 2014;133:e477–e489

INTRODUCTION

Fractures are the second most common injury caused by child physical abuse; bruises are the most common injury.¹ Failure to identify an injury caused by child abuse and to intervene appropriately may place a child at risk for further abuse, with potentially permanent consequences for the child.^{2–4} Physical abuse may not be considered in the physician's differential diagnosis of childhood injury because the caregiver may have intentionally altered the history to conceal the abuse.⁵ As a result, when fractures are initially evaluated, a diagnosis of child abuse may be missed.³ In children younger than 3 years, as many as 20% of fractures caused by abuse may be misdiagnosed initially as noninflicted or as attributable to other causes.³ In addition, fractures may be missed because radiography is performed before changes are obvious or the radiographic images are misread or misinterpreted.² However, incorrectly diagnosing physical abuse in a child with noninflicted fractures has serious consequences for the child and family. To identify child abuse as the cause of fractures, the physician must take into consideration the history, the age of the child, the location and type of fracture, the mechanism that causes the particular type of fracture, and the presence of other injuries while also considering other possible causes.

DIFFERENTIAL DIAGNOSIS OF FRACTURES**Trauma: Child Abuse Versus Noninflicted Injuries**

Fractures are a common childhood injury and account for between 8% and 12% of all pediatric injuries.^{6–8} In infants and toddlers, physical

abuse is the cause of 12% to 20% of fractures.⁹ Although unintentional fractures are much more common than fractures caused by child abuse, the physician needs to remain aware of the possibility of inflicted injury. Although some fracture types are highly suggestive of physical abuse, no pattern can exclude child abuse.^{10,11} Specifically, it is important to recognize that any fracture, even fractures that are commonly noninflicted injuries, can be caused by child abuse. Certain details that can help the physician determine whether a fracture was caused by abuse rather than unintentional injury include the history, the child's age and developmental stage, the type and location of the fracture, the age of the fracture, and an understanding of the mechanism that causes the particular type of fracture. The presence of multiple fractures, fractures of different ages or stages of healing, delay in obtaining medical treatment, and the presence of other injuries suspicious for abuse (eg, coexisting injuries to the skin, internal organs, or central nervous system) should alert the physician to possible child abuse.

Child's Age and Development

The physician should consider the child's age and level of development. Approximately 80% of all fractures caused by child abuse occur in children younger than 18 months,¹² and approximately one-quarter of fractures in children younger than 1 year are caused by child abuse.^{1,9,13–15} Physical abuse is more likely to be the cause of femoral fractures and humeral fractures in children who are not yet walking compared with children who are ambulatory,^{15–18} and the percentage of fractures caused by abuse declines sharply after the child begins to walk.^{9,19,20}

Fracture Specificity for Abuse

Fractures With High Specificity for Abuse

As shown in Table 1, certain fractures have high specificity for or strong association with child abuse, particularly in infants, whereas others may have less specificity.²¹ Rib fractures in infants, especially those situated posteromedially, and the classic metaphyseal lesions of long bones, have high specificity for child abuse. Fractures of the scapula, spinous process, and sternum also have high specificity for abuse but are uncommon.

Rib fractures are highly suggestive of child abuse. Most abusive rib fractures result from anterior-posterior compression of the chest. For this reason, rib fractures are frequently found in infants who are held around the chest, squeezed, and shaken. Rib fractures have high probability of being caused by abuse.^{15,17,21} The positive predictive value of rib fractures for child abuse in children younger than 3 years was 95% in one retrospective study.²² Other less common causes of rib fractures in infants include significant trauma sustained during childbirth or a motor vehicle crash as well as minor trauma

in infants who have increased bone fragility.^{23–25}

Cardiopulmonary resuscitation (CPR) has been proposed as a cause of rib fractures, but conventional CPR with 2 fingers of 1 hand rarely causes fractures in children.^{26,27} Recent recommendations that CPR be performed using 2 hands encircling the rib cage have raised concerns that this technique might cause rib fractures. An analysis of infants who were discovered during autopsy to have rib fractures and had received 2-handed chest compressions antemortem suggested that 2-handed CPR is associated with anterior-lateral rib fractures of the third to sixth ribs.²⁸ In this small study, no posterior rib fractures were observed. The fractures in these infants were always multiple, uniformly involved the fourth rib, and were sometimes bilateral. Additional research is needed to examine the relationship between the 2-handed CPR technique and rib fractures.

Classic metaphyseal lesions (CMLs) also have high specificity for child abuse when they occur during the first year of life.^{21,29} CMLs are the most common long bone fracture found in infants who die with evidence of inflicted injury.³⁰ CMLs are planar fractures through the primary spongiosa of the metaphysis. These fractures are caused when torsional and tractional shearing strains are applied across the metaphysis, as may occur with vigorous pulling or twisting of an infant's extremity.³¹ Fractures resembling CMLs radiographically have been reported after breech delivery³² and as a result of treatment of clubfoot.³³

Depending on the projection of the radiograph, CMLs can have the appearance of a corner or a bucket-handle fracture. Acute injuries can

TABLE 1 Specificity of radiologic findings in infants and toddlers¹⁹

High specificity ^a
CMLs

Digital fractures
Complex skull fractures
Common, but low specificity
Subperiosteal new bone formation
Clavicular fractures
Long-bone shaft fractures
Linear skull fractures

^a Highest specificity applies in infants.

be difficult to visualize radiographically. CMLs commonly heal without subperiosteal new bone formation or marginal sclerosis. They can heal quickly and be undetectable on plain radiographs in 4 to 8 weeks.³¹

Fractures With Moderate Specificity for Abuse

Although many children who have been abused will have only a single fracture,³⁴ the presence of multiple fractures, fractures of different ages and/or stages of healing, and complex skull fractures have moderate specificity for physical abuse. In addition, epiphyseal separations, vertebral body fractures, and digital fractures have moderate specificity for abuse. The presence of multiple fractures or fractures of different ages can be signs of bone fragility but should also evoke consideration of child abuse. Besides the predictive value of the particular pattern of fractures, many other factors, such as the history and the child's age, must be considered when determining whether the injury was inflicted.

Common Fractures With Low Specificity for Child Abuse

Long bone fractures (other than CMLs), linear skull fractures, clavicle fractures, and isolated findings of subperiosteal new bone formation have low specificity for child abuse. In contrast, the single long bone diaphyseal fracture is the most common fracture pattern identified in abused children.^{1,13,34}

An understanding of the extent and type of load that is necessary to cause a particular long bone fracture can help to determine whether a specific fracture is consistent with the injury described by the caregiver.^{35,36} Transverse fractures of the long bones are caused by the application of a bending load in a direction that is perpendicular

to the bone, whereas spiral fractures are caused by torsion or twisting of a long bone along its long axis. Oblique fractures are caused by a combination of bending and torsion loads.³⁷ Torus or buckle fractures are the result of compression from axial loading along the length of the bone. Although earlier studies suggested that spiral fractures should always raise suspicion for child abuse,¹² more recent studies do not show that any particular fracture pattern can distinguish between abuse and nonabuse with absolute certainty.^{16,38}

Falls are common in childhood.³⁹ Short falls can cause fractures, but they rarely result in additional significant injury (eg, neurologic injury).^{11,40–42} In a retrospective study of short falls, parents reported that 40% of the children before 2 years of age had suffered at least 1 fall from a height of between 6 inches and 4 feet. Approximately one-quarter of these children suffered an injury; bruises were the most common injury observed.⁴³

The femur, humerus, and tibia are the most common long bones to be injured by child abuse.^{1,34} Femoral fractures in the nonambulatory child are more likely caused by child abuse, whereas these fractures in ambulatory children are most commonly noninflicted.^{10,16,43–45}

Certain femur fractures may occur as a result of a noninflicted injury in young children. Several studies have demonstrated that a short fall to the knee may produce a torus or impacted transverse fracture of the distal femoral metaphysis.^{46,47} Oblique distal femur metaphyseal fractures have been reported in children playing in a stationary activity center, such as an Exersaucer (Evenflo, Picqua, OH).⁴⁸

In both ambulatory and nonambulatory children, under some circumstances, falls on a stairway can cause a spiral femoral fracture. For example, a fall

down several steps and landing with 1 leg folded or twisted underneath a child can lead to excessive torsional loading of the femur and a spiral fracture.⁴⁶ In ambulatory children, noninflicted femoral fractures have been described in children who fell while running or who fell and landed in a split-leg position.⁴³

A fracture of the humeral shaft in a child younger than 18 months has a high likelihood of having been caused by abuse.^{15,49,50} In contrast, supracondylar fractures in ambulatory children are usually noninflicted injuries resulting from short falls.¹⁵

Physicians should also be aware of a particular mechanism reported to produce a noninflicted spiral-oblique fracture of the humerus in 1 case report.⁵¹ When the young infant was rolled from the prone position to the supine while the child's arm is extended, the torsion and stress placed on the extended arm appeared to cause a spiral-oblique fracture of the midshaft of the humerus.

Linear skull fractures of the parietal bone are the most common skull fracture among young children, usually children younger than 1 year.¹³ A short fall from several feet onto a hard surface can cause a linear, nondiastatic skull fracture.^{19,52} The majority of linear skull fractures are not inflicted.⁵³ By contrast, complex or bilateral skull fractures are typical of nonaccidental trauma.

Syndromes, Metabolic Disorders, Systemic Disease

Preexisting medical conditions and bone disease may make a child's bones more vulnerable to fracture. Some conditions may manifest skeletal changes, such as metaphyseal irregularity and subperiosteal new bone formation. These entities should be considered in the differential diagnosis of childhood fractures.

Osteogenesis Imperfecta

Osteogenesis imperfecta (OI) is a heterogeneous family of diseases, usually caused by heterozygous mutations of the genes *COL1A1* and *COL1A2*,⁵⁴ but mutations in these and other genes can cause autosomal recessive forms of OI. The *COL1A1* and *COL1A2* genes encode the chains of type I collagen, which forms the structural framework of bone. Although it is a genetic disorder, many children have de novo mutations or autosomal-recessive disease and no family history of bone fragility. In addition, the presentation of the disease within affected members of the same family can be quite variable. Phenotypic expression of the disease depends on the nature of the mutation, its relative abundance attributable to mosaicism, and its expression in target tissues.⁵⁵ Some types of OI involve reduced production of collagen, and the symptoms resolve or lessen after puberty.⁵⁶ Table 2 lists the various signs and symptoms that can be present in a case of OI.

The diagnosis of OI is often suggested by a family history of fractures, short stature, blue sclera, poor dentition, and radiographic evidence of low bone density or osteopenia. The fractures are most commonly transverse in nature, occurring in the shafts of the

long bones. It is unusual to have multiple long bone fractures or rib fractures, particularly in infancy, without other clinical and radiographic evidence of OI.^{57,58}

OI has been misdiagnosed as child abuse.⁵⁹ On the other hand, OI is often suggested as the cause of fractures in children who have been abused. If fractures continue to occur when a child is placed in a protective environment, a more thorough evaluation for an underlying bone disease is needed. Child abuse is more common than OI,⁶⁰ and children with OI and other metabolic or genetic conditions may also be abused.^{61,62}

Preterm Birth

Preterm infants have decreased bone mineralization at birth, but after the first year of life, bone density normalizes.^{63,64} Osteopenia of prematurity has been well described as a complication in low birth weight infants.⁶⁵ Infants born at less than 28 weeks' gestation or who weigh less than 1500 g at birth are particularly vulnerable. Osteopenia of prematurity is multifactorial. Infants are also at risk if they receive prolonged (for 4 or more weeks) total parenteral nutrition, have bronchopulmonary dysplasia, and/or have received a prolonged course of diuretics or steroids.⁶⁶ Osteopenia commonly presents between 6 and 12 weeks of life. Osteopenia of prematurity can be ameliorated if infants are monitored closely and receive the nutritional and mineral supplementation initiated in the NICU.

Fractures associated with osteopenia of prematurity usually occur in the first year of life.⁶⁷ Rib fractures are typically encountered incidentally, whereas long bone fractures commonly present with swelling of the extremity. Osteopenia of prematurity can be associated with rickets, and in such cases, metaphyseal irregularities may be present.

Although osteopenia of prematurity may make the infant more vulnerable to fracture, preterm infants are also at an increased risk of abuse.⁶⁸

Vitamin D Deficiency Rickets

Suboptimal vitamin D concentrations and rickets have been proposed as causes of fractures in infants.⁶⁹ Vitamin D insufficiency in otherwise healthy infants and toddlers is common. Approximately 40% of infants and toddlers aged 8 to 24 months in an urban clinic had laboratory evidence of vitamin D insufficiency (serum concentrations of 25-hydroxyvitamin D of ≤ 30 ng/mL).⁷⁰ Prolonged breastfeeding without vitamin D supplementation was a critical factor that placed these infants at risk, although increased skin pigmentation and/or lack of sunlight exposure may also have contributed. Rickets is characterized by demineralization, loss of the zone of provisional calcification, widening and irregularity of the physis, and fraying and cupping of the metaphysis.⁷¹ Despite the high prevalence of vitamin D insufficiency in infants and toddlers, rickets is uncommon.⁷²

The claim that vitamin D deficiency or insufficiency causes skeletal lesions that lead to the incorrect diagnosis of child abuse in infants is not supported in the literature. A systematic clinical, laboratory, and radiologic assessment should exclude that possibility.^{73–75} Schilling et al found no difference in serum concentrations of 25-hydroxyvitamin D in young children with fractures suspicious for abuse and noninflicted fractures.⁷⁶ Vitamin D insufficiency was not associated with multiple fractures, in particular rib fractures or CMLs, the high specificity indicators of abuse. Perez-Rossello et al studied radiographs of 40 healthy older infants and toddlers with

TABLE 2 Characteristics of Osteogenesis Imperfecta

Fragile bones with few, some, or many of the following findings:
Poor linear growth
Macrocephaly
Triangular-shaped face
Blue sclerae
Hearing impairment as a result of otosclerosis
Hypoplastic, translucent, carious, late-erupting, or discolored teeth
Easy bruisability
Inguinal and/or umbilical hernias
Limb deformities
Hyperextensible joints
Scoliosis and/or kyphosis
Wormian bones of the skull
Demineralized bones

vitamin D insufficiency and deficiency and concluded that radiographic rachitic changes were uncommon and very mild. In this population, the reported fracture prevalence was zero.⁷²

In a study of 45 young children with radiographic evidence of rickets, investigators found that fractures occurred only in those infants and toddlers who were mobile.⁷⁷ Fractures were seen in 17.5% of the children, and these children were 8 to 19 months of age. The fractures involved long bones, anterior-lateral and lateral ribs, and metatarsal and metaphyseal regions. The metaphyseal fractures occurred closer to the diaphysis in the background of florid metaphyseal rachitic changes and did not resemble the juxtaphyseal corner or bucket handle pattern of the CML. In infant fatalities in which abuse is suspected, rachitic changes appear to be rare histologically.⁷⁸

Osteomyelitis

Osteomyelitis in infants can present as multiple metaphyseal irregularities potentially resembling CMLs.⁷⁹ Typically, the lesions become progressively lytic and sclerotic with substantial subperiosteal new bone formation. Other signs of infection are often present, such as fever, increased erythrocyte sedimentation rate, elevated C-reactive protein concentration, and elevated white blood cell count.

Fractures Secondary to Demineralization From Disuse

Any child with a severe disability that limits or prevents ambulation can be at risk for fractures secondary to disuse demineralization, even with normal handling.^{80,81} The fractures are usually diaphyseal rather than CMLs. Often, these fractures occur during physical therapy and range-of-motion exercises. It can be difficult to distinguish between

inflicted and noninflicted fractures occurring in these children. At the same time, children with disabilities are at an increased risk of being maltreated.^{82–84} When multiple or recurrent fractures occur in a disabled child, a trial change in caregivers may be indicated to determine whether the fractures can be prevented. This is an extreme intervention and should be reserved for unusual circumstances.⁶³

Scurvy

Scurvy is caused by insufficient intake of vitamin C, which is important for the synthesis of collagen. Although rare today because formula, human milk, fruits, and vegetables contain vitamin C, scurvy may develop in older infants and children given exclusively cow milk without vitamin supplementation and in children who eat no foods containing vitamin C.^{85–87} Although scurvy can result in metaphyseal changes similar to those seen with child abuse, other characteristic bone changes, including osteopenia, increased sclerosis of the zones of provisional calcification, dense epiphyseal rings, and extensive calcification of subperiosteal and soft tissue hemorrhages, will point to the diagnosis of scurvy.

Copper Deficiency

Copper plays a role in cartilage formation. Copper deficiency is a rare condition that may be complicated by bone fractures. Preterm infants are born with lower stores of copper than term infants, because copper is accumulated at a faster rate during the last trimester.⁸⁸ Copper insufficiency may be observed in children with severe nutritional disorders, for example, liver failure or short gut syndrome.⁸⁹ This deficiency is not likely to be observed in full-term children younger than 6 months of age or preterm infants younger than 2.5

months of age, because fetal copper stores are sufficient for this length of time. In addition, human milk and formula contain sufficient copper to prevent deficiency. Psychomotor retardation, hypotonia, hypopigmentation, pallor, and a sideroblastic anemia are some of the characteristic findings of copper deficiency in infants. Radiologic changes that should lead to further evaluation for possible deficiency include cupping and fraying of the metaphyses, sickle-shaped metaphyseal spurs, significant demineralization, and subperiosteal new bone formation.

Menkes Disease

Menkes disease, also known as Menkes kinky hair syndrome, is a rare congenital defect of copper metabolism.⁹⁰ Menkes disease is an X-linked recessive condition and occurs only in boys. Although it has many of the features of dietary copper deficiency, anemia is not associated with Menkes disease. Metaphyseal fragmentation and subperiosteal new bone formation may be observed on radiographs, and the findings may be difficult to distinguish from fractures caused by abuse.⁹¹ Other signs of Menkes disease include sparse, kinky hair, calvarial wormian bones, anterior rib flaring, failure to thrive, and developmental delay. A characteristic finding is tortuous cerebral vessels. Intracranial hemorrhage can occur in Menkes disease but has not been reported in infants with copper deficiency.

Systemic Disease

Chronic renal disease affects bone metabolism because children with chronic renal disease may develop a metabolic acidosis that interferes with vitamin D metabolism. Chronic renal disease can cause renal osteodystrophy resulting in the same radiographic changes as nutritional

rickets. Because chronic liver disease (eg, biliary atresia) interferes with vitamin D metabolism, such children may be at an increased risk of fractures. Fanconi syndrome, hypophosphatasia, hypophosphatemic (vitamin D resistant) rickets, hyperparathyroidism, and renal tubular acidosis also cause clinical variants of rickets.

Temporary Brittle Bone Disease Hypothesis

Physicians should be aware of alternative diagnoses that are unsupported by research but are sometimes suggested when an infant has unexplained fractures. In 1993, Paterson proposed that some infants may be born with bones that are temporarily more fragile or vulnerable to fracture in the context of normal handling, which he called “temporary brittle bone disease.”⁹² Paterson suggested that some trace element deficiency, such as copper or a transient collagen immaturity, caused the disease but provided no scientific data that confirmed his hypotheses and offered no specific test that confirmed temporary brittle bone disease.⁶¹ Subsequent studies did not support his hypotheses, and his case analysis has been refuted.^{57,93–95}

Miller hypothesized that temporary brittle bone disease is a result of fetal immobilization or intrauterine confinement that leads to transient bone loss or osteopenia.^{96,97} In support of his hypothesis, he reported that 95% of 21 infants with multiple unexplained fractures had decreased fetal movements, according to their mothers.^{97,98} Although he used bone densitometry in each patient as a basis for his conclusions, none of the patients had had bone densitometry performed at the time of the fracture. The testing was performed 8 to 21 weeks later, and no infants were tested before 5 months of age. In addition, bone densitometry standards have not been established

for infants. He relied on the mother's history of decreased fetal movements and provided no independent measurements of those movements. Palacios and Rodríguez found no evidence that oligohydramnios affects bone mass of the fetus, probably because fetal movement is only restricted in the last trimester of pregnancy by oligohydramnios and because the mechanical loading on the bones stimulating bone formation is conserved.⁹⁹

Medical Evaluation

History of Present Illness

It is essential to obtain a detailed history to determine how an injury occurred. If an injury in a nonverbal child was witnessed, the caregiver should be able to provide details about the child's activity and position before an injury and the child's final position and location after the injury occurred.⁴⁶ Verbal children with concerning fractures should be interviewed apart from caregivers and ideally by a professional who is skilled in forensic interviewing.

A comparison of the histories provided by caregivers of children with non-inflicted femoral fractures and by caregivers of children whose injuries were caused by abuse is instructive. When an injury was caused by abuse, the caregiver provided either no history of an injury or related a history of a low-energy event. By contrast, 29% of the caregivers of children with non-inflicted injuries provided some high-energy explanation, such as a motor vehicle collision or that the child fell from a height.¹⁶ Most of the low-energy mechanisms provided for the noninflicted injuries involved falls including stair falls and siblings landing on the femur during play.^{16,46}

The child's response to the event may also provide important clues about the etiology. The majority of children with long bone fractures will have

some swelling, pain, or other signs, such as decreased use of the extremity, suggesting a fracture.^{100,101} Some children, however, will have minimal external signs of injury.¹⁰² The absence of any history of injury, a vague description of the event, a delay in seeking care, the absence of an explanation for an injury particularly in a nonambulatory child, or an inconsistent explanation should increase the physician's concern that an injury was caused by child abuse (see Table 3).^{13,16}

Past Medical History

The past medical history is important and should include details about the mother's pregnancy. If the child was born preterm, the infant's bone mineral content may be reduced, and the infant may be at risk for fracture. A history of total parental nutrition, hepatobiliary disease, diuretic therapy, hypercalciuria, or corticosteroids may make the bones of a low birth weight infant even more vulnerable to fracture. In addition, chronic diseases, such as renal insufficiency or metabolic acidosis, malabsorption, cerebral palsy or other neuromuscular disorders, genetic diseases that affect skeletal development, or any illness that limits mobility, may affect bone strength. A thorough dietary history and history of medications that can

TABLE 3 When Is a Fracture Suspicious for Child Abuse?

- No history of injury
- History of injury not plausible—mechanism described not consistent with the type of fracture, the energy load needed to cause the fracture, or the severity of the injury
- Inconsistent histories or changing histories provided by caregiver
- Fracture in a nonambulatory child
- Fracture of high specificity for child abuse (eg, rib fractures)
- Multiple fractures
- Fractures of different ages
- Other injuries suspicious for child abuse
- Delay in seeking care for an injury

predispose to fractures are important. The physician should inquire about previous injuries including bruises and determine the child's developmental abilities, because children who are not yet mobile are much more likely to have fractures caused by abuse.

Family History

A family history of multiple fractures, early-onset hearing loss, abnormally developed dentition, blue sclera, and short stature should suggest the possibility of OI.

Social History

The physician should obtain a complete psychosocial history, including asking who lives in the home and who has provided care for the child. The history should inquire about intimate partner violence, substance abuse including drugs and alcohol, mental illness, and previous involvement with child protective services and/or law enforcement.

Physical Examination

The child should have a comprehensive physical examination, and the growth chart should be carefully reviewed. Abnormal weight may suggest neglect or endocrine or metabolic disorders. Any signs or symptoms of fractures, such as swelling, limitation of motion, and point tenderness should be documented. The physician should do a complete skin examination to look for bruises and other skin findings because bruises are the most common injury caused by child abuse. The majority of children with fractures do not have bruising associated with the fracture; the presence or absence of such bruising does not help to determine which fractures are caused by child abuse.^{103,104} Bruising in a child who is not yet cruising or bruising in unusual locations, such as the ears,

neck, or trunk should raise suspicion for child abuse.^{105,106} The child should be examined for other injuries caused by child abuse, in addition to signs of other medical conditions associated with bone fragility. Blue sclerae are seen in certain types of OI. Sparse, kinky hair is associated with Menkes disease. Dentinogenesis imperfecta is occasionally identified in older children with OI.

Laboratory Evaluation

The clinical evaluation should guide the laboratory evaluation. In children with fractures suspicious for abuse, serum calcium, phosphorus, and alkaline phosphatase should be reviewed, although alkaline phosphatase may be elevated with healing fractures. The physician should consider checking serum concentrations of parathyroid hormone and 25-hydroxyvitamin D, as well as urinary calcium excretion (eg, random urinary calcium/creatinine ratio) in all young children with fractures concerning for abuse, but these levels should certainly be assessed if there is radiographic evidence of osteopenia or metabolic bone disease. Screening for abdominal trauma with liver function studies as well as amylase and lipase concentration should be performed when severe or multiple injuries are identified. A urinalysis should be performed to screen for occult blood. Serum copper, vitamin C, and ceruloplasmin concentrations should be considered if the child is at risk for scurvy or copper deficiency and has radiographic findings that include metaphyseal abnormalities.

If OI is suspected, sequence analysis of the *COL1A1* and *COL1A2* genes that are associated with 90% of cases of OI as well as other genes associated with less common autosomal-recessive forms of OI may be more sensitive than biochemical tests of

type I collagen and may identify the mutation to guide testing of other family members.¹⁰⁷ Some of the less common forms of OI are OI types IIB and VII, *CRTAP*; OI type VI, *FKBP10*; OI type VIII, *LEPRE1*; OI type IX, *PP1B*; OI type X, *SERPINH1*; OI type XI, *SP7*; OI type XII, *SERPINF1*; and OI type XIII, *BMP1*. DNA sequencing can be performed using genomic DNA isolated from peripheral blood mononuclear cells or even saliva, whereas the biochemical analysis of type I collagen requires a skin biopsy. Doing both DNA analysis and skin biopsy is not indicated in most cases. Consultation with a pediatric geneticist may be helpful in deciding which children to test and which test to order.¹⁰⁸

Imaging Approach

Children younger than 2 years with fractures suspicious for child abuse should have a radiographic skeletal survey to look for other bone injuries or osseous abnormalities.¹⁰⁹ Additional fractures are identified in approximately 10% of skeletal surveys, with higher yields in infants.¹¹⁰ Skeletal surveys may be appropriate in some children between ages 2 and 5 years, depending on the clinical suspicion of abuse. If specific clinical findings indicate an injury at a particular site, imaging of that area should be obtained regardless of the child's age.

The American College of Radiology has developed specific practice guidelines for skeletal surveys in children.¹¹¹ Twenty-one images are obtained, including frontal images of the appendicular skeleton, frontal and lateral views of the axial skeleton, and oblique views of the chest. Oblique views of the chest have been shown to increase the sensitivity, specificity, and accuracy of the identification of rib fractures.¹¹² A full 4 skull series should be obtained if there are concerns of

head injury. Computed tomography (CT) 3-dimensional models are valuable adjuncts to the radiographs and have the potential to replace the skull series.¹¹³ This has not been studied systematically in this context, however. Because lateral views of the extremities increase yield, some authors suggest that these views be included in the imaging protocol.¹¹⁴ Fractures may be missed if the guidelines are not followed or if the images are of poor quality.¹¹⁵ A repeat skeletal survey should be performed approximately 2 to 3 weeks after the initial skeletal survey if child abuse is strongly suspected.^{109,116} The follow-up examination may identify fractures not seen on the initial skeletal survey, can clarify uncertain findings identified by the initial skeletal survey, and improves both sensitivity and specificity of the skeletal survey.^{116,117} In one study, 13 of 19 fractures found on the follow-up examination were not seen on the initial series.¹¹⁶ The number of images on the follow-up examination may be limited to 15 views by omitting the views of the skull, pelvis, and lateral spine.¹¹⁸

Radiography may assist in assessing the approximate time when an injury occurred because long bone fractures heal following a particular sequence.¹¹⁹ If the healing pattern is not consistent with the explanation provided, the accuracy of the explanation should be questioned.

Bone scintigraphy may be used to complement the skeletal survey but should not be the sole method of identifying fractures in infants. Although it has high overall sensitivity, it lacks specificity for fracture detection and may fail to identify CMLs and skull fractures.^{109,119,120} Scintigraphy does have high sensitivity for identifying rib fractures, which can be difficult to detect before healing. In toddlers and older children, the use of bone scintigraphy or skeletal survey depends on

the specific clinical indicators of abuse.¹⁰⁹

Because brain injuries are often occult, head imaging should be considered for any child younger than 1 year with a fracture suspicious for abuse.¹²¹ Imaging studies may help clarify whether the child has been abused, provide further support for a diagnosis of child abuse, and identify other injuries that require treatment. Additional imaging may be needed if the child has signs or symptoms of chest, abdominal, or neck injury.

Chest CT can identify rib fractures that are not seen on chest radiographs.¹²² CT is particularly useful in detecting anterior rib fractures and rib fractures at all stages of healing—early subacute, subacute, and old fractures. Although CT may be more sensitive in identifying these injuries, a chest CT exposes the child to significantly more radiation than chest radiography. Every effort should be made to reduce children's exposure to radiation while at the same time considering the risk to the child if abuse is not identified.¹²³ Therefore, selective application of this technique in certain clinical settings is appropriate.

Other modalities may become available in the future that will provide more accurate identification of skeletal injuries. Whole-body short tau inverse recovery imaging, a magnetic resonance imaging (MRI) technique, may identify rib fractures not recognized on the radiographic skeletal survey.¹²⁴ In a study of 21 infants with suspected abuse, whole-body MRI at 1.5-Tesla was insensitive in the detection of CMLs and rib fractures. In some cases, whole-body MRI identified soft tissue edema and joint effusions that led to the identification of skeletal injuries with additional radiographs.¹²⁵ Bone scintigraphy with ¹⁸F-sodium fluoride positron emission tomography (¹⁸F-NaF PET) bone scan may be useful in cases

of equivocal or negative skeletal surveys when there is high clinical suspicion of abuse. If available, a ¹⁸F-NaF positron emission tomography bone scan has better contrast and spatial resolution than ^{99m}Tc-labeled methylene diphosphonate.¹²⁰

Although bone densitometry by dual-energy x-ray absorptiometry is useful to predict bone fragility and fracture risk in older adults, interpretation of bone densitometry in children and adolescents is more problematic.¹²⁶ In adults, bone densitometry is interpreted using T scores, which describe the number of SDs above or below the average peak bone mass for a gender- and race-adjusted reference group of normal subjects. Because peak bone mass is not achieved until approximately 30 years of age, in children, z scores must be used to express bone density, because z scores express the child's bone mineral density as a function of SDs above or below the average for an age- and gender-matched norm control population.¹²⁷ In addition, because bone size influences dual-energy x-ray absorptiometry, z scores must also be adjusted for height z scores.¹²⁸ The International Society for Clinical Densitometry recommends that the diagnosis of osteoporosis in childhood should not be made on the basis of low bone mass alone but should also include a clinically significant history of low-impact fracture. The recommendations currently apply to children 5 years and older, although reference data are available for children as young as 3 years.^{129,130} Unfortunately, there are limited reference data for the young, nonverbal child who is most at risk for suffering fractures caused by child abuse.

Evaluation of Siblings

Siblings, especially twins, and other young household members of children who have been physically abused

should be evaluated for maltreatment.¹³¹ In a study of 795 siblings in 400 households of a child who had been abused or neglected, all siblings in 37% of households and some siblings in 20% of households had suffered some form of maltreatment.¹³² In this study, which included all manifestations of maltreatment, siblings were found to be more at risk for maltreatment if the index child suffered moderate or severe maltreatment. In addition to a careful evaluation, imaging should be considered for any siblings younger than 2 years, especially if there are signs of abuse.

DIAGNOSIS

When evaluating a child with a fracture, physicians must take a careful history of any injury event and then determine whether the mechanism described and the severity and timing are consistent with the injury identified (see Table 3).¹³³ They must consider and evaluate for possible diagnoses in addition to other signs or symptoms of child abuse. A careful evaluation for other injuries is important because the presence of additional injuries that are associated with child abuse increases the likelihood that a particular fracture was inflicted.^{16,43} It is important to remember that even if a child has an underlying disorder or disability that could increase the likelihood of a fracture, the child may also have been abused because children with disabilities and other special health care needs are at increased risk of child abuse.^{83,84} Physicians should keep an open mind to the possibility of abuse and remember that child abuse occurs in all socioeconomic

groups and across all racial and ethnic groups. Many of these diagnoses are complex. If a physician is uncertain about how to evaluate an injury or if they should suspect a fracture was caused by child abuse, they should consult a child abuse pediatrician or multidisciplinary child abuse team to assist in the evaluation, particularly if the child is nonambulatory or younger than 1 year of age.¹³⁴ In certain circumstances, the physician will need to consult an orthopedist, endocrinologist, geneticist, or other subspecialists.

All US states, commonwealths, and territories have mandatory reporting requirements for physicians and other health care providers when child abuse is suspected. Physicians should be aware of and comply with the reporting requirements of their state. Typically, the standard for making a report is when the reporter “suspects” or “has reason to believe” that a child has been abused or neglected. Sometimes determining whether that “reasonable belief” or “reasonable suspicion” standard has been met can be nuanced and complex. The physician should keep in mind that incontrovertible proof of abuse or neglect is not required by state statutes, and there may be cases in which it is reasonable to consult with a child abuse pediatrician about whether a report should be made.

CLINICAL REPORT

Fluoride Use in Caries Prevention in the Primary Care Setting

abstract

FREE

Dental caries remains the most common chronic disease of childhood in the United States. Caries is a largely preventable condition, and fluoride has proven effectiveness in the prevention of caries. The goals of this clinical report are to clarify the use of available fluoride modalities for caries prevention in the primary care setting and to assist pediatricians in using fluoride to achieve maximum protection against dental caries while minimizing the likelihood of enamel fluorosis. *Pediatrics* 2014;134:626–633

Dental caries (ie, tooth decay) is an infectious disease in which acid produced by bacteria dissolves tooth enamel. If not halted, this process will continue through the tooth and into the pulp, resulting in pain and tooth loss. This activity can further progress to local infections (ie, dental alveolar abscess or facial cellulitis), systemic infection, and, in rare cases, death. Dental caries in the United States is responsible for many of the 51 million school hours lost per year as a result of dental-related illness, which translates into lost work hours for the parent or adult caregiver.¹ Early childhood caries is the single greatest risk factor for caries in the permanent dentition. Good oral health is a necessary part of overall health, and recent studies have demonstrated the adverse effects of poor oral health on multiple other chronic conditions, including diabetes control.² Therefore, the failure to prevent caries has health, educational, and financial consequences at both the individual and societal level.

Dental caries is the most common chronic disease of childhood,¹ with 59% of 12- to 19-year-olds having at least 1 documented cavity.³ Caries is the “silent epidemic” that disproportionately affects poor, young, and minority populations.¹ The prevalence of dental caries in very young children increased during the period between the last 2 national surveys, despite improvements for older children.⁴ Because many children do not receive dental care at young ages, and risk factors for dental caries are influenced by parenting practices, pediatricians have a unique opportunity to participate in the primary prevention of dental caries. Studies show that simple home and primary care setting prevention measures would save health care dollars.⁵

Development of dental caries requires 4 components: teeth, bacteria, carbohydrate exposure, and time. Once teeth emerge, they may become colonized with cariogenic bacteria. The bacteria metabolize carbohydrates

and create acid as a byproduct. The acid dissolves the mineral content of enamel (demineralization) and, over time with repeated acid attacks, the enamel surface collapses and results in a cavity in the tooth. Protective factors that help to remineralize enamel include exposing the teeth to fluoride, limiting the frequency of carbohydrate consumption, choosing less cariogenic foods, practicing good oral hygiene, receiving regular dental care, and delaying bacterial colonization. If carious lesions are identified early, the process can be halted or reversed by modifying the patient's individual risk and protective factors. Certain American Academy of Pediatrics (AAP) publications (*Oral Health Risk Assessment Timing and Establishment of the Dental Home*⁶ and *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents*⁷) discuss these concepts in greater depth and provide targeted preventive anticipatory guidance. The Medical Expenditure Panel Survey demonstrated that 89% of infants and 1-year-olds have office-based physician visits annually, compared with only 1.5% who have dental visits.⁸ For primary prevention to be effective, it is imperative that pediatricians be knowledgeable about the process of dental caries, prevention of the disease, and available interventions, including fluoride.

Fluoride is available from many sources and is divided into 3 major categories: tap water (and foods and beverages processed with fluoridated water), home administered, and professionally applied. There has been substantial public and professional debate about fluoride, and myriad information is available, often with confusing or conflicting messages. The widespread decline in dental caries in many developed countries, including the United States, has been largely attributable to the use of fluoride. Fluoride has 3 main mechanisms of action: (1) it promotes enamel remineralization; (2) it

reduces enamel demineralization; and (3) it inhibits bacterial metabolism and acid production.⁹ The mechanisms of fluoride are both topical and systemic, but the topical effect is the most important, especially over the life span.¹⁰

RISK OF FLUOROSIS

The only scientifically proven risk of fluoride use is the development of fluorosis, which may occur with fluoride ingestion during tooth and bone development. Fluorosis of permanent teeth occurs when fluoride of sufficient quantity for a sufficient period of time is ingested during the time that tooth enamel is being mineralized. Fluorosis is the result of subsurface hypomineralization and porosity between the developing enamel rods.¹¹ This risk exists in children younger than 8 years, and the most susceptible period for permanent maxillary incisor fluorosis is between 15 and 30 months of age.^{12–14} The risk of fluorosis is influenced by both the dose and frequency of exposure to fluoride during tooth development.¹⁵ Recent evidence also suggests that individual susceptibility or resistance to fluorosis includes a genetic component.¹⁶

After 8 years of age, there is no further risk of fluorosis (except for the third molars) because the permanent tooth enamel is fully mineralized. The vast majority of enamel fluorosis is mild or very mild and characterized by small

white striations or opaque areas that are not readily noticeable to the casual observer. Although this type of fluorosis is of no clinical consequence, enamel fluorosis has been increasing in frequency over the last 2 decades to a rate of approximately 41% among adolescents because fluoride sources are more widely available in varied forms.¹⁷ Moderate and severe forms of enamel fluorosis are uncommon in the United States but have both an aesthetic concern and potentially a structural concern, with pitting, brittle incisal edges, and weakened groove anatomy in the permanent 6-year molars.

In 2001, the AAP endorsed the guidelines from the Centers for Disease Control and Prevention (CDC), "Recommendations for Using Fluoride to Prevent and Control Dental Caries in the United States."¹⁵ Dental and governmental organizations (American Dental Association [ADA], American Academy of Pediatric Dentistry, the Department of Health and Human Services, and the CDC) have more recently published guidelines on the use of fluoride, but current AAP publications do not reflect these newer evidence-based guidelines. Table 1 provides a simple explanation of fluoride use for patients at low and high risk of caries.

The present report has 2 goals: (1) to assist pediatricians in using fluoride to achieve maximum protection against

TABLE 1 Summary of Fluoride Modalities for Low- and High-Risk Patients

Fluoride Modality	Low Caries Risk	High Caries Risk
Toothpaste	Starting at tooth emergence (smear of paste until age 3 y, then pea-sized)	Starting at tooth emergence (smear of paste until age 3 y, then pea-sized)
Fluoride varnish	Every 3–6 mo starting at tooth emergence	Every 3–6 mo starting at tooth emergence
Over-the-counter mouth rinse	Not applicable	Starting at age 6 y if the child can reliably swish and spit
Community water fluoridation	Yes	Yes
Dietary fluoride supplements	Yes, if drinking water supply is not fluoridated	Yes, if drinking water supply is not fluoridated

dental caries while minimizing the likelihood of enamel fluorosis; and (2) to clarify the advice that should be given by pediatricians regarding fluoride in the primary care setting.

CURRENT INFORMATION REGARDING FLUORIDE USE IN CARIES PREVENTION

The following information aims to assist pediatricians in achieving maximum protection against dental caries for their patients while minimizing the likelihood of enamel fluorosis. Sources of ingested fluoride include drinking water, infant formula, fluoride toothpaste, prescription fluoride supplements, fluoride mouth rinses, professionally applied topical fluoride, and some foods and beverages.¹⁸

Fluoride Toothpaste

Fluoride toothpaste has consistently been proven to provide a caries-preventive effect for individuals of all ages.^{15,19} In the United States, the fluoride concentration of over-the-counter toothpaste ranges from 1000 to 1100 ppm. In some other countries, toothpastes containing 1500 ppm of fluoride are available. A 1-inch (1-g) strip of toothpaste translates to 1 or 1.5 mg of fluoride, respectively. A pea-sized amount of toothpaste is approximately one-quarter of an inch. Therefore, a pea-sized amount of toothpaste containing 1000/1100 ppm of fluoride would have approximately 0.25 mg of fluoride, and the same amount of toothpaste containing 1500 ppm of fluoride would have approximately 0.38 mg of fluoride. Most fluoride toothpaste in the United States contains sodium fluoride, sodium monofluorophosphate, or stannous fluoride as the active ingredient. Parents should supervise children younger than 8 years to ensure the proper amount of toothpaste and effective brushing technique. Children younger than 6 years are more likely to ingest some or all of the toothpaste

used. Ingestion of excessive amounts of fluoride can increase the risk of fluorosis. This excess can be minimized by limiting the amount of toothpaste used and by storing toothpaste where young children cannot access it without parental help.

Use of fluoride toothpaste should begin with the eruption of the first tooth. When fluoride toothpaste is used for children younger than 3 years, it is recommended that the amount be limited to a smear or grain of rice size (about one-half of a pea). Once the child has turned 3 years of age, a pea-sized amount of toothpaste should be used.^{20,21} Young children should not be given water to rinse after brushing because their instinct is to swallow. Expecting without rinsing will both reduce the amount of fluoride swallowed and leave some fluoride in the saliva, where it is available for uptake by the dental plaque. Parents should be strongly advised to supervise their child's use of fluoride toothpaste to avoid overuse or ingestion.

High-concentration toothpaste (5000 ppm) is available by prescription only. The active ingredient in this toothpaste is sodium fluoride. This agent can be recommended for children 6 years and older and adolescents who are at high risk of caries and who are able to expectorate after brushing. Dentists may also prescribe this agent for adolescents who are undergoing orthodontic treatment, as they are at increased risk of caries during this time.²²

Fluoride Varnish

Fluoride varnish is a concentrated topical fluoride that is applied to the teeth by using a small brush and sets on contact with saliva. Advantages of this modality are that it is well tolerated by infants and young children, has a prolonged therapeutic effect, and can be applied by both dental and non-

dental health professionals in a variety of settings.²³ The concentration of fluoride varnish is 22 600 ppm (2.26%), and the active ingredient is sodium fluoride. The unit dose packaging from most manufacturers provides a specific measured amount (0.25 mg, providing 5 mg of fluoride ion). The application of fluoride varnish during an oral screening is of benefit to children, especially those who may have limited access to dental care. Current American Academy of Pediatric Dentistry recommendations for children at high risk of caries is that fluoride varnish be applied to their teeth every 3 to 6 months.²⁴ The 2013 ADA guideline recommends application of fluoride varnish at least every 6 months to both primary and permanent teeth in those subjects at elevated caries risk.²⁵ The US Preventive Services Task Force recently published a new recommendation that primary care clinicians apply fluoride varnish to the primary teeth of all infants and children starting at the age of primary tooth eruption (B recommendation).²⁶

In most states, Medicaid will pay physicians for the application of fluoride varnish. Information regarding fluoride varnish application reimbursement and which states currently provide payment can be found on the AAP Web site (<http://www2.aap.org/oralhealth/docs/OHReimbursementChart.pdf>) and the Pew Charitable Trusts Web site (<http://www.pewstates.org/research/analysis/reimbursing-physicians-for-fluoride-varnish-85899377335>). Because state regulations vary regarding whether fluoride varnish must be applied within the context of a preventive care code, this information should be determined before billing.

Indications for Use

In the primary care setting, fluoride varnish should be applied to the teeth of all infants and children at least once every 6 months and preferably every 3 months, starting when the first tooth

erupts and until establishment of a dental home.

Instructions for Use

Fluoride varnish must be applied by a dentist, dental auxiliary professional, physician, nurse, or other health care professional, depending on the practice regulations in each state. It should not be dispensed to families to apply at home. Application of fluoride varnish is most commonly performed at the time of a well-child visit. Teeth are dried with a 2-inch gauze square, and the varnish is then painted onto all surfaces of the teeth with a brush provided with the varnish. Children are instructed to eat soft foods and not to brush their teeth on the evening after the varnish application to maximize the contact time of the varnish to the tooth. The following day, they should resume brushing twice daily with fluoridated toothpaste.

Over-the-Counter Fluoride Rinse

Over-the-counter fluoride rinse provides a lower concentration of sodium fluoride than toothpaste or varnish. The concentration is most commonly 230 ppm (0.05% sodium fluoride). Expert panels on this topic have concluded that over-the-counter fluoride rinses should not be recommended for children younger than 6 years because of their limited ability to rinse and spit and the risk of swallowing higher-than-recommended levels of fluoride.²⁷ A teaspoon (5 mL) of over-the-counter fluoride rinse contains approximately 1 mg of fluoride. For children younger than 6 years, this type of rinse provides an additional, low-dose topical fluoride application that may assist in the prevention of enamel demineralization. However, the evidence for an anticaries effect is limited. The daily use of a 0.05% sodium fluoride rinse may be of benefit for children older than 6 years who are at high risk of dental caries; however, there is no additional benefit

beyond daily use of fluoridated toothpaste for children at low risk of caries.^{28,29}

Dietary Fluoride Supplements

Dietary fluoride supplements should be considered for children living in communities in which the community water is not fluoridated or who drink well water that does not contain fluoride.²⁶ Because there are many sources of fluoride in the water supply and in processed food, it is essential that all potential sources of fluoride be assessed before prescribing a dietary supplement, including consideration of differing environmental exposures (eg, dual homes, child care). As a general guideline, if the primary source of water is fluoridated tap or well water, the child will not require fluoride supplementation, even if he or she primarily drinks bottled water, because the teeth are exposed to fluoride through cooking and brushing. The risk of fluorosis is high if fluoride supplements are given to a child consuming fluoridated water.³⁰ Information about the fluoridation levels in many community water systems can be found on the CDC Web site entitled *My Water's Fluoride* (<http://apps.nccdc.gov/MWF/Index.asp>). Not all communities report this information to the CDC; therefore, it may be necessary to contact the local water department to determine the level of fluoride in the community water. Well water must be tested for fluoride content before prescribing supplements; such testing is available in most states through the state or county public health laboratory.

Guidelines for Use

CDC recommendations regarding fluoride supplementation are provided in Table 2. Supplements can be prescribed in liquid or tablet form. Tablets are preferable for children old enough to chew, because they gain an additional topical benefit to the teeth during the chewing process. Liquid supplements are recommended for younger children and should ideally be added to water or put directly into the child's mouth. Addition of the fluoride supplement to milk or formula is not recommended because of the reduced absorption of fluoride in the presence of calcium.³¹ The risk of mild fluorosis can be minimized by health care providers verifying that there are no other sources of fluoride exposure before prescribing systemic fluoride supplements.

Other Sources of Fluoride

Fluoride is present in processed foods and beverages and may be naturally occurring in some areas of the country. The presence of fluoride in juices and carbonated beverages does not counteract the cariogenic nature of these beverages.

Reconstitution of Infant Formula

In a study of infant feeding practices, 70% to 75% of mothers who fed their infants formula used tap water to reconstitute the powdered formula.³² According to CDC data from 2012, approximately 67% of US households using public water supplies received

TABLE 2 Fluoride Supplementation Schedule for Children

Age	Fluoride Ion Level in Drinking Water ^a		
	<0.3 ppm	0.3–0.6 ppm	>0.6 ppm
Birth–6 mo	None	None	None
6 mo–3 y	0.25 mg/d ^b	None	None
3–6 y	0.50 mg/d	0.25 mg/d	None
6–16 y	1.0 mg/d	0.50 mg/d	None

Source: Centers for Disease Control and Prevention.⁴³

^a 1.0 ppm = 1 mg/L.

^b 2.2 mg of sodium fluoride contains 1 mg of fluoride ion.

optimally fluoridated water (between 0.7 and 1.2 ppm).³³

ADA Evidenced-Based Clinical Recommendations

In 2011, the ADA Council on Scientific Affairs examined the existing evidence and made 2 recommendations. The first recommendation supported the continued use of optimally fluoridated water to reconstitute powdered and liquid infant formula, being cognizant of the small risk of fluorosis in permanent teeth. The second recommendation stated that if there was concern about the risk of mild fluorosis, the formula could be reconstituted with bottled (nonfluoridated) water.¹⁸ It should be noted that most bottled water has suboptimal levels of fluoride and that fluoride content is not listed unless it is added.

Community Water Fluoridation

Community water fluoridation is the practice of adding a small amount of fluoride to the water supply. It has been heralded as 1 of the top 10 public health achievements of the 20th century by the CDC.³⁴ Community water fluoridation is a safe, efficient, and cost-effective way to prevent tooth decay and has been shown to reduce tooth decay by 29%.³⁵ It prevents tooth decay through the provision of low levels of fluoride exposure to the teeth over time and provides both topical and systemic exposure. It is estimated that every dollar invested in water fluoridation saves \$38 in dental treatment costs (<http://www.cdc.gov/fluoridation/benefits/>). Currently, although more than 210 million Americans live in communities with optimally fluoridated water, there are more than 70 million others with public water systems who do not have access to fluoridated water.³³ The fluoridation status of a community water supply can be determined by contacting the local water department

or accessing the Web site My Water's Fluoride (<http://apps.nccd.cdc.gov/MWF/Index.asp>).

Recommended Concentration

Water fluoridation was initiated in the United States in the 1940s. In January 2011, the US Department of Health and Human Services proposed a change to lower the optimal fluoride level in drinking water. The proposed new recommendation is 0.7 mg of fluoride per liter of water to replace the previous recommendation, which was based on climate and ranged from 0.7 mg/L in the warmest climates to 1.2 mg/L in the coldest climates.³⁶ The change was recommended because recent studies showed no variation in water consumption by young children based on climate and to adjust for an overall increase in sources of fluoride (foods and beverages processed with fluoridated water and fluoridated mouth rinses and toothpastes) in the American diet.

Evidence Supporting Community Water Fluoridation

Despite overwhelming evidence supporting the safety and preventive benefits of fluoridated water, community water fluoridation continues to be a controversial and highly emotional issue. Opponents express a number of concerns, all of which have been addressed or disproven by validated research. The only scientifically documented adverse effect of excess (nontoxic) exposure to fluoride is fluorosis. An increase in the incidence of mild enamel fluorosis among teenagers has been cited as a reason to discontinue fluoridation, even though this condition is cosmetic with no detrimental health outcomes. Recent opposition has sometimes centered on the question of who decides whether to fluoridate (elected/public officials or the voters), possibly reflecting a recent trend of distrust of the US government. Many opponents believe fluoridation to be mass medication and

call the ethics of community water fluoridation into question, but courts have consistently held that it is legal and appropriate for a community to adopt a fluoridation program.³⁷ Opponents also express concern about the quality and source of fluoride, claiming that the additives (fluorosilicic acid, sodium fluoride, or sodium fluorosilicate), in their concentrated form, are highly toxic and are byproducts of the production of phosphate fertilizer and may include other contaminants, such as arsenic. The quality and safety of fluoride additives are ensured by Standard 60 of the National Sanitation Foundation/American National Standards Institute, a program commissioned by the Environmental Protection Agency (EPA), and testing has been conducted to confirm that arsenic or other substances are below the levels allowed by the EPA.³⁸ Finally, there have been many unsubstantiated or disproven claims that fluoride leads to kidney disease, bone cancer, and compromised IQ. More than 3000 studies or research papers have been published on the subject of fluoride or fluoridation.³⁹ Few topics have been as thoroughly researched, and the overwhelming weight of the evidence—in addition to 68 years of experience—supports the safety and effectiveness of this public health practice.

Naturally Occurring Fluoride in Drinking Water

The optimal fluoride level in drinking water is 0.7 to 1.2 ppm, an amount that has been proven beneficial in reducing tooth decay. Naturally occurring fluoride may be below or above these levels in some areas. Under the Safe Drinking Water Act (Pub L No. 93-523 [1974]), the EPA requires notification by the water supplier if the fluoride level exceeds 2 ppm. In areas where naturally occurring fluoride levels in drinking water exceed 2 ppm, people should consider an alternative water source or home water treatments to reduce the risk of

fluorosis in young children.⁴⁰ Well water should be tested for the level of fluoride; this testing is most commonly performed through the health department.

Fluoride Toxicity

Toxic levels of fluoride are possible, particularly in children, as a result of ingesting large quantities of fluoride supplements. The toxic dose of elemental fluoride is 5 to 10 mg of fluoride per kilogram of body weight.⁴¹ Lethal doses in children have been calculated to be between 8 and 16 mg/kg. When prescribing sodium fluoride supplements, it is recommended to limit the quantity prescribed at one time to no more than a 4-month supply. Parents should be advised to keep fluoride products out of the reach of young children and to supervise their use.

Fluoride Removal Systems

There are a number of water treatment systems that are effective in the removal of fluoride from water,⁴² including reverse osmosis and distillation. Parents should be counseled on the use of these and activated alumina filters in the home and, should they choose to use one that removes fluoride, the potential effect on their family's oral health. Commonly used home carbon filters (eg, Brita [Brita LP, Oakland, California], PUR [Kaz USA, Incorporated, Southborough, MA]) do not remove fluoride. These can be recommended for families who are concerned about heavy metals or other impurities in their home water supply but who wish to retain the benefits of fluoridated water.

SUGGESTIONS FOR PEDIATRICIANS

1. Know how to assess caries risk. As recommended by the AAP's *Oral Health Risk Assessment Timing and Establishment of the Dental Home*⁶ and *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents*,⁷ pediatricians should perform oral health risk assessments on all children at preventive visits beginning at 6 months of age. An oral health risk assessment tool has been developed by the AAP/Bright Futures and endorsed by the National Interprofessional Initiative on Oral Health. This tool can be accessed at <http://www2.aap.org/oralhealth/RiskAssessment-Tool.html>. There are currently no validated early childhood caries risk assessment tools. The aforementioned tool is a guide to help clinicians counsel patients about oral health and best identify risk.
2. Know how to assess a child's exposure to fluoride and determine the need for topical or systemic supplements.⁴³
3. Understand indications for fluoride varnish and how to provide it. Fluoride varnish can be a useful tool in the prevention of early childhood caries. Additional training on oral screenings, fluoride varnish indications and application, and office implementation can be found in the Smiles for Life Curriculum Course 6: Caries Risk Assessment, Fluoride Varnish and Counseling⁴⁴ at www.smilesforlifeoralhealth.org. In addition, the AAP Children's Oral Health Web site

is a resource for oral health practice tools (<http://www2.aap.org/oralhealth/PracticeTools.html>).

4. Advocate for water fluoridation in the local community. Public water fluoridation is an effective and safe method of protecting the most vulnerable members of our population from dental caries. Pediatricians are encouraged to advocate on behalf of public water fluoridation in their communities and states. For additional information and water fluoridation facts and detailed questions and answers, see http://www.ada.org/sections/newsAndEvents/pdfs/fluoridation_facts.pdf, <http://www.cdc.gov/fluoridation/>, and <http://www.ilikemyteeth.org>.

High-deductible health plans (HDHPs) are insurance policies with higher deductibles than conventional plans. The Medicare Prescription Drug Improvement and Modernization Act of 2003 linked many HDHPs with tax-advantaged spending accounts. The 2010 Patient Protection and Affordable Care Act continues to provide for HDHPs in its lower-level plans on the health insurance marketplace and provides for them in employer-offered plans. HDHPs decrease the premium cost of insurance policies for purchasers and shift the risk of further payments to the individual subscriber. HDHPs reduce utilization and total medical costs, at least in the short term. Because HDHPs require out-of-pocket payment in the initial stages of care, primary care and other outpatient services as well as elective procedures are the services most affected, whereas higher-cost services in the health care system, incurred after the deductible is met, are unaffected. HDHPs promote adverse selection because healthier and wealthier patients tend to opt out of conventional plans in favor of HDHPs. Because the ill pay more than the healthy under HDHPs, families with children with special health care needs bear an increased cost burden in this model. HDHPs discourage use of nonpreventive primary care and thus are at odds with most recommendations for improving the organization of health care, which focus on strengthening primary care.

This policy statement provides background information on HDHPs, discusses the implications for families and pediatric care providers, and suggests courses of action. *Pediatrics* 2014;133:e1461–e1470

INTRODUCTION

High-deductible health plans (HDHPs) have been in existence for many years and were formally codified in 2003 by the Medicare Prescription Drug Improvement and Modernization Act (Pub L No. 108-173). They have become more prevalent in recent years and continue to grow rapidly. The early results of the Patient Protection and Affordable Care Act (ACA) of 2010 (Pub L No. 111-148) indicate that HDHPs will continue to proliferate. Therefore, it is appropriate for the American Academy of Pediatrics (AAP) to revisit HDHPs and their effects on health care for children. This policy statement seeks to enhance understanding of the basic principles of an HDHP, to evaluate how this model comports with the principles of the AAP in providing health care for children, and to make recommendations as to how (and whether) an HDHP should be implemented. Because research data on HDHPs are scarce on many points, as others have observed, “until better evidence emerges, policy

makers and employers will have to use the best available information and commonsense strategies.”¹

DESCRIPTION

For an existing HDHP to receive governmental approval, the plan must have a minimum deductible for 2013 of \$1250 for an individual and \$2500 for a family, with total out-of-pocket expenses (not including the cost of premiums) not to exceed \$6250 for an individual and \$12 500 for a family.² Because pure HDHP policies could discourage use of preventive services, to mitigate this effect, federal law requires HDHPs to cover basic preventive services—well-patient visits, immunizations, screening tests, and Bright Futures preventive services—with no deductibles and no copays.

An optional modification provided by the law is the addition of either a health reimbursement arrangement (HRA), which can be applied to any type of health insurance, or a health savings account (HSA), which is applicable only to an HDHP policy (Table 1).² Both HRAs and HSAs consist of tax-free funds that can be used to pay for out-of-pocket costs (except copays) not paid for by the insurance plan. In 2013, HSA contributions are limited to \$3250 for self-only coverage and \$6450 for family coverage. The mechanics of how funds are withdrawn and how the costs are paid—for instance, by special-purpose debit card or convenience checks that draw down the account—vary depending on the plan.

An HRA is both funded and owned by the employer. If the employee leaves

employment, the funds revert to the employer, unless the employer opts to make them portable. At the discretion of the employer, unused funds may be carried over from year to year.

An HSA is funded by the subscriber, the employer, or both. The HSA account is owned by the subscriber, not the employer, and can move with the subscriber in the event of job change or retirement. In addition, HSA funds can be invested for interest or other gains, and those gains are not taxable. Unused HSA funds can be rolled over into an individual retirement account at age 65.

It is important to understand that if the HRA or HSA is funded by the employer at a sufficiently high level (“fully funded”), patients will not actually suffer financial harm, compared with conventional policies (ie, preferred provider organization, health maintenance organization, point of service, and indemnity plans). Instead, these features will simply induce patients to make a market calculation in seeking care because the need to tap into the savings account resource will be a much more palpable event as compared with the invisible use of resources with conventional policies. It is not known how well funded HRAs and HSAs have been, but common experience indicates that full funding of the accounts is unusual. The average HSA account balance was \$1879 at the end of 2012; the average HSA account balance for accounts opened in 2005 was \$4688.³

HDHPs are becoming a more predominant form of health insurance in the United States as they are increasingly offered by employers and

chosen by subscribers. Although preferred provider organization plans remain the most common offerings by employers and cover more than one-half of covered employees, a 2013 report found that 20% of small companies and 40% of large companies offered an HDHP plan to its employees, and 20% of all employers offered HDHP plans as the only choice.⁴ Whereas in 2006, only 4% of employees were covered by HDHP plans, that number is approximately 20% in 2013. One estimate is that 27% of HDHP enrollees are younger than 20 years.⁵ It is estimated that more than 5 million people younger than 20 years are enrolled in HDHP plans. The health insurance marketplace, under the ACA, offers HDHP plans in the lower tiers, and the ACA allows HDHPs to continue to be offered by employers, so the number of patients covered by HDHP plans is expected to grow further.

Historically, enrollees who have chosen HDHP plans have represented a healthier, wealthier, and better-educated segment of the population. In one study, 64% of HDHP households declared themselves in excellent or very good health, and 89% earned \$50 000 or more per year.⁶ Increasingly, however, HDHPs are being offered by companies with a predominance of low-income workers. In 2012, 44% of covered workers at companies with many low-wage workers faced an annual deductible of \$1000 or more, compared with 29% at firms with many high-wage workers. Across all employers, 34% of insured workers faced a deductible of at least \$1000, with 14% required to pay a deductible of at least \$2000 annually.⁷ Some plans exceed the federal limits for copays or deductibles and are, thus, ineligible for adding the HRA or HSA features; whether they conform or not, however, all HDHP plans have the effect of shifting liability from the insurer to the insured.

TABLE 1 Comparison of HRAs and HSAs

Plan	Tax Savings	Funded by	Annual Rollover of Unused Funds	Portable
HRA	Yes	Employer	At the employer's discretion	At the employer's discretion
HSA	Yes (funds may be invested and earn interest tax free)	Employers and/or employees	Yes	Yes

HDHPs: FOR AND AGAINST

HDHPs represent a market-based approach to one segment of health care: the initial stages of care. In evaluating this approach, it is necessary to look at the detailed effects of HDHPs in practice as well as theory. Because of the scarcity of research data, it is necessary to use inferences and common experience of participants in the field as well as research findings.

For HDHPs

The rise in health care costs has placed unrelenting pressure on employers, who remain the primary purchasers of health insurance products, and on individual purchasers as well. HDHPs offer a simple way to reduce the cost of premiums.

There have been many ideas for health care reform that would reduce total costs, but many of these ideas would be complex to enact, would require the cooperation of many who have vested interests and might be at financial risk from the reforms, and would require legislative authorization. By contrast, HDHPs are simple to implement, requiring the agreement of only the insurance company and the purchaser and no other stakeholder. In addition, legislation authorizing tax exemption for HSAs and HRAs was enacted in 2003. Simplicity of implementation is, no doubt, one of the most attractive aspects of HDHPs.

Employers, employees, and individual subscribers welcome the lower premium level of HDHP plans. Patients tend to accept HDHP deductibles and copays as familiar features, although the levels are higher than in conventional plans. Employees tend not to make the calculation that the financial risk of illness is being transferred to them from the insurer and the business owner. (As HDHP subscribers increased from 2007 to 2011, "Total per capita spending on employer-

sponsored insurance grew at an average annual rate of 4.9 percent ... [and] out-of-pocket medical spending increased at an average annual rate of 8.0%."*) Both individual subscribers and employees who are confident of their ability to make medical choices and to withstand the financial risk may find HDHPs a reasonable choice, especially if linked to an HSA or HRA. Even if they are not confident of their continued good health or medical navigational skill, subscribers of modest means can find the HDHP premium their only affordable choice and may judge running the financial risk of HDHPs preferable to being uninsured.

In addition to these practical considerations, HDHPs have been justified on a theoretical basis. With conventional private insurance, patients are shielded from the financial effect of their purchases when they seek care at the early stages of illness. As a result, patients may use more of the services than they would if they had to pay the actual cost of the services. By contrast, HDHPs require a family to confront the market price of health care services at the point of purchase—a primary care or specialty visit, a laboratory test, or a hospitalization. With "skin in the game," it is hypothesized that patients will have incentive to seek less care for minor reasons, to seek more high-quality and low-cost services, or perhaps to adopt a healthier lifestyle (eg, exercise more, lose weight, improve nutrition, abstain from or reduce smoking and alcohol consumption) to avoid medical expenditures. Because of the patient's direct exposure to the financial consequences of seeking care and his or her expected responses to this burden, HDHPs have been called consumer-directed health plans.⁹

There is evidence that patients with HDHPs do consume less health care than those in other plans.^{10–13} Patients

with HDHPs are prescribed generic drugs more often than other patients, make fewer visits to specialists, are less frequently hospitalized, and have fewer visits to doctors for episodes of illness and make fewer visits within those episodes.¹² HDHPs seem to reduce overall health care costs significantly.¹² How much the employer saves on HDHP policies depends on both the level of HRA or HSA funding and the utilization behavior of the patients. It seems clear, however, that total employer costs of HDHP plans are less than with conventional plans.

There is ample anecdotal evidence from knowledgeable consumers, especially medical professionals, that HDHPs have worked well for their personal health care insurance. They have been able to save money individually and for their office staff/personnel as they advise them on health care decisions, by canny utilization of the system. When they avoid visits for minor illnesses or avoid tests that seem to be an overreach of care, money accumulates in their HSA accounts. When their families are healthy, they reap the reward. Their above-average wealth allows them to withstand the risk of unexpected expenditures for illness. Although less sophisticated consumers may not be able to make such decisions, the HDHP model works for many in this specific group.

Against HDHPs

While acknowledging the success of HDHPs in reducing expenditures, at least in the short term, critics of HDHPs find many flaws with the HDHP strategy.

Appropriateness of Preferentially Decreasing Initial and Lower-Cost Care

Although most agree that cost reduction in the American health care system is essential, HDHP critics insist

that constraining “first-dollar” expenditures by excluding these costs from insurance support, while leaving the higher-cost items covered and thus unconstrained, is a poor choice. Virtually all policies today have deductibles, but the expanded level of the deductible under HDHPs means that a majority of patients will find all their primary care costs to be fully out-of-pocket (except for preventive visits), along with costs that flow from primary care encounters, such as tests, imaging services, medications, and specialty office visits. In addition, because of the higher deductible limit, many procedures will now be encompassed in the out-of-pocket domain, such as hernia repairs, tympanostomy tube placement, and even procedures such as pectus excavatum surgery.

The reason the American health care system is so expensive, however, is not generally considered to be expenditures in the low-cost sector, which represent the majority of encounters. Hospitals, procedures, prescription drugs, and imaging are generally considered the major culprits of the

high cost of medical care, rather than ordinary office services. Increasingly, health policy analysts are assigning the high cost of care to high prices even more than high utilization.¹⁴ The HDHP focus on the low-cost segment of care would thus appear to be misplaced.

Moreover, a significant amount of costs are incurred by a small percentage of high-cost patients. “Nearly two-thirds of health care costs are concentrated in 10% of patients, so to control costs, the focus needs to be on these patients, not the 50% of the population that is relatively healthy and uses just 3% of the health care dollar”¹⁵ (see Fig 1). A way to decrease costs for these patients would be to supply more initial and primary care, not less.¹⁶

The conclusion, then, would be that although cost reduction is important, a better solution than curtailing costs at the low end would be curtailing costs at the high end and with high-intensity users, which are exactly the areas in which deductibles are ineffective.

Lack of Concurrence Between HDHPs and the National Strategy on Health Care Organization

Most health policy experts agree that the United States suffers from insufficient primary care and a surfeit of specialty care.^{17,18} Evidence also indicates that primary care should be the foundation of a highly functional health care system.¹⁹ Primary care is widely thought to be an essential service that, if well-used, saves money for the system. Prescriptions for waste reduction in the medical care system generally exempt primary care and have never targeted primary care for children.²⁰ Although studies have not shown great savings from preventive services, it is reasonable to assume that primary prevention and early detection of disease decrease morbidity and associated costs. It is also widely assumed that having a ready source of primary care prevents excessive use of emergency departments.^{21,22} Starfield asserted that “Several international studies have confirmed the importance of ... low

FIGURE 1

Cumulative distribution of personal health care spending, 2009. Reproduced with permission from National Institute for Health Care Management Foundation analysis of data from the 2009 Medical Expenditure Panel Service.

or no cost sharing for primary care services.”²³

One policy response to the need for buttressing primary care has been the patient-centered medical home (PCMH).²⁴ The PCMH is essentially a strengthened primary care office with highly personal care, greater nurse outreach and team care, an emphasis on preventive services and patient registries, education about self-care, and guidance and coordination through the medical care system. The AAP supports the PCMH model and believes that the activated primary care office will be an important component of improved health care organization.²⁵

There are many potential negative effects, however, that HDHPs could have on the strategy of increasing the capacity of American primary care. HDHPs reduce the resources that could and should be invested in primary care; fewer resources expended in a sector will inevitably lead to its degradation. The PCMH strategy requires more resources rather than fewer. In addition, it is widely recognized that 2 prime deterrents to choosing a career in primary care are the imbalance of specialty/primary incomes and the difficulty of managing primary care offices. HDHPs only exacerbate both of these influences (see next section).

Specific Effects on Primary Care

Although HDHPs affect more than just primary care, primary care is perhaps unique in its reliance on relatively small payments for a large number of patients as well as the absence of higher-priced procedures. Expanding the deductible to HDHP levels makes nearly all primary care visits throughout the year (except for preventive visits) subject to out-of-pocket payments. HDHPs will, thus, have a uniquely heavy effect on primary care (as well as cognitive specialty services), making it important to define the effects.

As rational consumers, families confronted with high deductibles will often search for strategies to minimize their out-of-pocket expenditures. They may forgo visits and access information of questionable reliability from sources such as the Internet, neighbors, and the like. They may attempt to substitute telephone conversations for face-to-face visits. They may postpone needed consultations in an effort to address concerns only at well-child visits that are exempt from deductibles. They may decide not to accept physician recommendations for testing or referrals or for follow-up visits to monitor the progress of a disease process. These consumer tactics will affect both health outcomes and processes for patients as well as the operations of the primary care office. In addition, postponement of visits can contribute to the physician's risk of the most common outpatient malpractice complaint—failure to diagnose serious disease early.²⁶

Even though HDHPs offer full coverage of preventive visits without reference to the deductible, HDHP patients tend to stint on preventive care, including immunizations.¹⁰ It is reasonable to believe that early detection of disease suffers, although there have been no studies on that important subject. Continuity of care and the doctor–patient relationship suffer as primary care visits are discouraged and efforts to fulfill the requirements of PCMHs are eroded. Even if a visit would not have revealed serious illness, the calming effect of reassurance to a worried family is part and parcel of excellent medical care, frequently not only allaying anxiety but also averting further use of medical resources, and to the extent that these visits are discouraged, an essential facet of medical care is undermined.

In addition to the effects of HDHPs on care itself, HDHPs also impede the functioning of a pediatric primary care

office. Although the literature might not explore these specifics, they are readily apparent to practicing physicians. Substituting telephone calls for office visits increases practice overhead and decreases income. Excessive discussions of costs increase visit times and, thus, overhead, a point that advocates for spending time discussing finances with patients ignore.²⁷ Bundling sick visits into preventive visits increases the time per visit and may decrease the quality of either the preventive service or the illness service or both, and it is difficult for the office to receive payment for this extra service, despite it being warranted by *Current Procedural Terminology* coding rules.

Finally, it is common experience that billing costs and bad debts are exacerbated by HDHPs. It is usually impossible to know how much a patient will owe for a visit at the checkout station because insurance company Web sites are most often problematic in delivering information that includes both the allowed charge and the deductible remaining. The method of accessing an HRA or HSA account is often opaque. Repeated billings are often necessary, with the attendant overhead, and patients are not infrequently unwilling to pay once they are away from the office and the service, and they are angry that their substantial premiums do not cover all their medical bills. Although some of these factors apply to all insurance, with HDHPs, they recur throughout the year.

Effects on Those Not Choosing HDHPs—Adverse Selection

HDHPs promote adverse selection to health insurance pools as healthier patients gravitate toward the lower premium price HDHP plans, leaving disproportionate numbers of sicker, higher-cost patients. As a result, patients in

conventional plans will pay higher premiums because patients opting for HDHP plans will not be contributing fully to the common pool.

Quality of Care With HDHPs

Although the previous discussion has included observations of quality of care, it seems appropriate to reiterate these effects here. Once again, a lack of studies hampers this effort, but inferences can, nonetheless, be made. Patients frequently make poorly informed decisions in the medical care marketplace. Many of the reductions in care, not only office visits but also tests and consultations, hospitalizations, emergency care, and use of generic drugs in some cases, may be unwarranted.²⁸ One study has shown that patients of modest means postpone visits to emergency departments for serious illnesses.²⁸ This phenomenon is especially pronounced in males.²⁹ A report on Medicare patients has shown that increased cost-sharing has led to decreased physician visits and prescriptions but also to a higher rate of hospitalization.³⁰ Pediatric surgeons report informally that many patients defer elective but important procedures because of cost under an HDHP plan (personal communication, Mary Brandt, MD, professor of surgery and pediatrics, October 12, 2013). Continuity of care and the doctor–patient relationship suffer as primary care visits are discouraged under HDHPs, fewer patients receive preventive care, and fewer patients are fully immunized.¹² The ability of PCMHs to fulfill their mission is undermined. It stands to reason that with increased barriers to seeking initial care, some diagnoses and treatments of illnesses will be delayed. Haviland et al, advocates of HDHPs (referred to as consumer-directed health plans), concede that “for all populations, enrollment in [consumer-directed health plans] ... leads to reductions in care that is

considered beneficial.”¹³ In short, there are many reasons to think that HDHPs decrease quality of care and few to think that they increase it.

HDHPs and Market Mechanisms

HDHP critics question whether market mechanisms are capable of achieving the outcomes that HDHP advocates would wish. Many patients agree with the critics and think that shopping for health care is confusing and inappropriate.³¹ There appear to be many discrepancies between theory and actuality.

A well-functioning market requires well-informed consumers to make rational choices, but many believe that the highly specialized nature of medical decision making, coupled with the profound information asymmetries and uncertainties that characterize these interactions, undermine the ability of market mechanisms to effectively function as expected.³² Certainly, urgent situations are not compatible with “careful shopping,” and the emotional distress accompanying acute illness often compromises rational decision making.³³

Although in the aggregate, patients in HDHPs consume fewer health care resources in response to higher out-of-pocket expenditures, whether this consumption pattern is beneficial remains an open question, as the previous discussion of quality of care under HDHPs illustrates.

There is some evidence that patients tend to equate higher price with higher quality.³⁴ One study indicated that when confronted with a complicated benefit structure, patients often make suboptimal choices.³⁵ An example of this situation is that 80% of patients with HDHPs are unaware that their policies mandate coverage of preventive services free of the deductible or copays (supplying at least part of the explanation for poor prevention

and immunization statistics under HDHPs).³⁶ Patients with chronic illnesses forgo care because of cost.³⁷ Poorer families choose to forgo care more often than families with higher income.³⁸

Market mechanisms depend critically on price signals for consumers to be able to make market decisions, but few prices from clinicians, laboratories, or specialized and diagnostic services are publicly available online or even by request to the office.³⁹ Indeed, prices negotiated between practices and health plans are confidential by the terms of the contract. In addition, the price of a visit is uncertain beforehand, because the level of the service rendered by the physician cannot be predicted. On the other hand, because generic drugs are used more frequently and tests and hospitalizations are used less frequently than with conventional plans, one can surmise that when the primary care physician is involved in the decision making, costs can be alleviated. Economist Victor Fuchs commented, “The idea of sick patients shopping for the lowest-price medical care ... is a fantasy.”⁴⁰

Finally, critics of HDHPs suggest that because patients lack medical knowledge, one of the most important functions of the primary care physician is to guide the patient in choosing among health care options. Thus, it would seem counterintuitive to encourage laypeople not to use the professional knowledge and judgment of a primary care physician, especially when a primary care visit is perhaps the least expensive encounter in the entire spectrum of health care services.

Aspects of HDHPs That Apply Specifically to Children

In health care financing, as with pediatric health care, children are not simply smaller adults. Unfortunately, there is little research on the specific

effects of HDHPs on children. Nonetheless, certain features of these plans pose significant concerns.

Families with small children tend to be high users of primary care services. As such, HDHPs would seem to be particularly inappropriate for them. Because young families are often struggling financially, they will be particularly prone to choosing the lower-premium HDHP plan but then be torn whether to make a visit for a sick child. As noted earlier, the statistics of lower use of preventive visits and lower immunization rates is sobering. Pediatrics places special emphasis on children with special health care needs. These children and their families are specifically disadvantaged by HDHPs. If the family is insured by an HDHP, they will experience higher health care costs than under conventional insurance. If they instead obtain conventional insurance, the premiums and payments they face will be higher because of adverse selection—that is, patients without special needs will be paying less into the common pot.

In addition, some have suggested that there might be legal and ethical aspects to enrolling children in HDHPs. Although adults may be free to take chances with their own lives and health care, the state has a recognized function in protecting children. There is a risk in delaying health care that is exacerbated by financial considerations. It is possible for adults to delay seeking care for their children that turns out to have been necessary. Foreseeing this situation, it might be in the state's interest to disallow HDHPs for children.

Finally, health care for a child costs, on average, about half that for an adult younger than 65 years and approximately one-quarter to one third that for a Medicare patient. The problems of the excessive cost of American health care can hardly be attributed to

children. It would seem to make sense, then, to save money on children's health care only where it is clearly ineffective and inefficient. That public policy in America favors adults and the elderly over children has been well documented; saving on health care of children while the bills of the elderly are unconstrained would seem to be foolish.

The Flow of Resources Within Medical Care Sectors

A subtle point of economic theory is worth mentioning. If HDHPs put pressure on initial care, but there is no such force on the higher-cost items experienced by higher-intensity patients, commercial innovation and research will favor the area where funds flow more freely. Costs will thus not be constrained in the areas where they most need to be, and less effort will be spent on innovation in primary care, which already lacks sufficient attention.

Disparities

Disparities in access, service, and outcomes have been a persistent concern of the AAP and health policy analysts. It is therefore important to reflect on the effect of HDHPs on disparities. If an HDHP plan is linked to a highly funded HRA or HSA, there should be little difference in access between HDHPs and conventional plans. To the extent that the HRA or HSA is less well funded, however, patients who experience high costs and patients who have lower income will experience a higher percentage of their incomes devoted to health care. In some states, the coverage envisioned under the ACA could be as high as 8% to 27% of income for a family of 4 whose income is 200% of the federal poverty level.²¹ Although income effects are not the only cause of disparities, the effects of HDHPs will be to exacerbate the effects of disparate wealth, both by

making HDHP policyholders less able to seek care and by making the premiums of conventional policies more expensive because of adverse selection.

To be more clear: even under the ACA, patients with low incomes—either 100% of the federal poverty level or less or 133% of the federal poverty level or less (depending on the state)—will be eligible for Medicaid. Their access to care will not be limited financially, although it will be constrained by the number of providers accepting Medicaid patients. For patients who have private insurance, the difference in ability to obtain care will depend on the level of their incomes. Higher-income patients will be only somewhat impeded by financial constraints, but those who are just over the Medicaid-eligible line will find the financial constraints more daunting. In other words, it will be the people in the middle, those “just making it” financially, who will feel most strongly the tension of balancing worry over needed care with worry over money. The conclusion, therefore, can be drawn that HDHPs not accompanied by fully funded HRAs or HSAs contribute to disparity of access to care on the basis of income.^{28,38}

SUMMARY

HDHPs are an understandable response by the insurance industry and employers to the rising cost of health care. The major effect of HDHPs is to incentivize patients to balance the perceived need for initial care against the cost before the deductible is met. HDHPs have led to lower expenditures on care by their subscribers. Sophisticated medical care utilizers and healthy and higher-income patients can save significant amounts of money under HDHPs. High funding by employers of HRA and HSA plans can ensure that patients as well as employers benefit.

Critics point out that the lower-cost sectors of health care are less important for

cost savings than higher cost areas that are unaffected by HDHPs; that lower-cost patients are affected by HDHPs, but higher-cost patients are more of a cost problem; that primary care is affected negatively by HDHPs, which goes against established health policy goals; that health care quality might be negatively affected by HDHPs; that health care disparities may be accentuated by HDHPs; that using a market mechanism to induce more patient choice might be inappropriate; and that HDHPs might be particularly inappropriate for children, who are a lower-cost population than adults and who are large utilizers of primary care.

RECOMMENDATIONS

The AAP cautions that HDHPs may be a less desirable way to lower health care costs than other means that can be found, even if “other means” require more work by government, insurance companies, and other health policy participants. Consideration should be given to mandating that HDHPs be offered only to adults and not children.

Benefit Design

1. HDHP policies should permit a generous number of primary care visits to be allowed without the deductible each year or that outpatient visits be exempted from the deductible, as is proposed by the Bipartisan Policy Center for Medicare patients.⁴¹ A list of other important and beneficial services and procedures usually provided by medical subspecialists that would be exempted from HDHP deductibles should be compiled. Examples might be insertion of tympanostomy tubes, appendectomy, and reduction and casting of fractures, for instance.
2. If children are to continue to be offered HDHP coverage, insurers

should define children with certain diagnoses as “children with special needs” using the Maternal and Child Health Bureau’s definition, and eliminate the burden of a deductible for these children.

3. HSA and HRA health savings accounts should be required to be funded at high levels by the purchasing employers.
4. All elements of the PCMH should be included in the plan benefit package and paid, without application of the deductible, appropriate to the relative value units, including telephone and electronic communication services. Insurers should cover and pay appropriately for all services described by the *Current Procedural Terminology* manual.

Insurance Company Administrative Policies

1. Insurance companies issuing HDHP policies should be required to devise procedures so that medical offices can easily and rapidly determine the complete bill of the patient at the time of a visit, enabling the office to try to pursue proper collection from the patient at the time of the visit.
2. Patients with HSA and HRA accounts should be issued debit or credit cards that allow medical offices to access the accounts at the time of service.
3. Because practices will incur significant additional overhead costs in administering HDHPs, insurance companies should compensate practices for those costs. One alternative would be to pay practices per-patient-per-month overhead allowances.
4. Insurers should take positive steps to emphasize the importance of preventive visits to its policyholders and to inform them that such services are not subject to the de-

ductible or copays. Plans should be held responsible for continually assessing the completeness of preventive services utilization by its policyholders and to take appropriate steps as conditions warrant.

5. Because of the complexity of HDHP plans, especially when one considers that each company would have its own specific rules and procedures, insurance companies should ensure that they enable both patients and providers to understand provisions. Handouts for the offices and Web site explanations should be available in real time. Insurance companies should have specifically assigned representatives for each office for general issues and should be able to deal with problems in real time, and insurers should facilitate training of office staff members in handling HDHPs. Materials for patients should specifically counsel patients not to stint on primary care services, especially preventive services.

Actions by the Primary Care Offices

1. A staff member in each office should be knowledgeable enough about HDHPs to be able to explain the concept and the details to a potentially confused patient. Patient handouts describing HDHPs and especially the fact that preventive care is not subject to copays or a deductible would be helpful.
2. Offices should continue to give feedback on problems with HDHPs to the AAP by using the Hassle Factor forms (available online at My AAP at www.aap.org/moc, see More Resources).

Alternative Cost-Reduction Strategies

1. Policy makers should continue to devise alternative strategies that will

reduce costs in ways that do not negatively affect primary care. Examples include reduction of high prices rather than utilization, particularly of hospitals, procedures, pharmaceuticals, and medical devices⁴²; offering incentives and support to practices to serve high utilizers with intensive primary care; increasing use of hospices and decreasing use of ICUs for end-of-life care; promoting accountable care organizations; promoting centers of excellence⁴³; developing further value-based insurance plans; increasing use of publicly reported physician report cards for both primary care and specialists issued by independent practice associations as well as hospitals and medical groups;

enacting tort reform; and many other strategies.^{44,45}

Legislation

1. State governments should take steps to make the knowledge of prices for services at various institutions readily available to the public and primary care offices.
2. The federal government should consider restricting HDHP plans to those older than 18 years.

Research

1. Significant efforts to study the effects of HDHPs, especially on children, should be made. The potential foci of research are multifold and deserving of a report solely

devoted to the topic of the specific needs for research on HDHPs.

CLINICAL REPORT

Hypothermia and Neonatal Encephalopathy

abstract

FREE

Data from large randomized clinical trials indicate that therapeutic hypothermia, using either selective head cooling or systemic cooling, is an effective therapy for neonatal encephalopathy. Infants selected for cooling must meet the criteria outlined in published clinical trials. The implementation of cooling needs to be performed at centers that have the capability to manage medically complex infants. Because the majority of infants who have neonatal encephalopathy are born at community hospitals, centers that perform cooling should work with their referring hospitals to implement education programs focused on increasing the awareness and identification of infants at risk for encephalopathy, and the initial clinical management of affected infants. *Pediatrics* 2014;133:1146–1150

BACKGROUND

In 2005, the National Institute of Child Health and Human Development (NICHD) convened a workshop to evaluate the status of knowledge regarding the safety and efficacy of hypothermia as a neuroprotective therapy for neonatal hypoxic-ischemic encephalopathy.¹ Shortly thereafter, the Committee on Fetus and Newborn of the American Academy of Pediatrics published a commentary supporting the recommendation of the workshop that the widespread implementation of hypothermia outside the limits of controlled trials was premature.² In 2010, the *Eunice Kennedy Shriver* NICHD organized a follow-up to the 2005 workshop to review available evidence.³ The purpose of this clinical report is to review briefly the current knowledge regarding the efficacy and safety of therapeutic hypothermia, to point out major gaps in knowledge that were identified at the 2010 workshop, and to suggest a framework for the implementation of hypothermia. The intended audience is neonatal/perinatal medicine practitioners.

PRELIMINARY STUDIES

Neuronal rescue of encephalopathic newborn infants using induced hypothermia is one of the few therapeutic modalities in neonatology that was studied extensively in animal models before clinical application in humans. From animal studies, it was noted that cooling the brain to approximately 32°C to 34°C starting within 5.5 hours after a hypoxic/ischemic insult and continuing to cool for 12 to 72 hours resulted in improved neuropathologic and functional outcomes.⁴ After showing consistent benefit in animal models, the safety, feasibility, and practicality of using induced hypothermia in infants who have neonatal encephalopathy were investigated in

several small studies. Data from these preliminary clinical studies indicated that reducing body temperature by 2°C to 3°C for a prolonged period of time was possible and that the changes in blood pressure, heart rate, and cardiac output noted were of little clinical significance.^{5–7}

Large Randomized Clinical Trials of Hypothermic Neural Rescue (Table 1)

Six large randomized clinical trials of induced hypothermia for neonatal

encephalopathy were published from 2005 to 2011.^{8–13} Although there were some differences in the method of cooling and selection of subjects, in all trials infants were at least 35 weeks' gestation at birth; randomization was completed within 6 hours of birth; the target temperature was 33.5°C to 34.5°C; the intervention period was 72 hours, followed by slow rewarming (0.5°C/hour); and the primary outcome measure was the combined rate of death or disability, assessed at 18 to 22 months of age. Some trials used preferential head

cooling with mild body cooling,^{8,11} and others used whole-body cooling^{9,10,12,13}; however, all trials continuously monitored both the degree of cooling and core body temperature. In addition, 3 trials used either amplitude-integrated electroencephalography (aEEG) or electroencephalography (EEG) for the assessment of severity of encephalopathy and enrollment of infants.^{8,10,12}

Each of the 6 published trials was powered to detect a difference in the primary composite outcome of death or disability at 18 to 24 months of age, and all showed a benefit with cooling; in 4 of the 6 studies, this reached statistical significance. Rates of death or disability were similar in the control groups for 4 of the 6 studies, suggesting that patient selection and treatment were likely similar in these trials.^{8–10,13} A published meta-analysis that included a small pilot study⁵ as well as the 6 large published clinical trials demonstrated a reduction in the relative risk (RR) of the composite outcome of death or major neurodevelopmental disability at 18 to 24 months of age by 24% (RR, 0.76; 95% confidence interval [CI], 0.69–0.84).¹⁴ A beneficial effect was noted both in infants who had moderate encephalopathy (RR, 0.67; 95% CI, 0.56–0.81) and those who had severe encephalopathy (RR 0.83; 95% CI, 0.74–0.92). The number of infants who need to be treated to prevent 1 infant from dying or becoming disabled is 6 for infants who have moderate encephalopathy and 7 for those who have severe encephalopathy. A review by the Cochrane collaboration that included 11 randomized controlled trials comprising 1505 term and late preterm infants who had moderate/severe encephalopathy demonstrated similar results.¹⁵ The reduction in death or major neurodevelopmental disability to 18 months of age for treated infants was 25% overall; 32% for infants who had moderate encephalopathy and

TABLE 1 Therapeutic Hypothermia Clinical Trials

Clinical Trial	Entry Criteria
CoolCap	Gestational age ≥ 36 weeks and ≤ 6 hours of age AND Apgar score ≤ 5 at 10 minutes after birth OR Continued need for resuscitation at 10 minutes after birth OR pH < 7.00 or base deficit ≥ 16 mmol/L or more on an umbilical cord blood sample or an arterial or venous blood sample obtained within 60 minutes of birth AND Moderate or severe encephalopathy on clinical examination AND Moderately or severely abnormal background of at least 20 minutes' duration or seizure activity on amplitude integrated electroencephalogram (aEEG) after one hour of age
Whole Body Cooling	Gestational age ≥ 36 weeks and ≤ 6 hours of age AND pH ≤ 7.00 or base deficit ≥ 16 mmol/L in an umbilical cord blood sample or any blood sample obtained within the first hour after birth^a AND Moderate or severe encephalopathy on clinical examination
TOBY	Gestational age ≥ 36 weeks and ≤ 6 hours of age AND Apgar score ≤ 5 at 10 minutes after birth OR Continued need for resuscitation 10 minutes after birth OR pH < 7.00 or base deficit ≥ 16 mmol/L on umbilical cord or arterial or capillary blood sample obtained within 60 minutes after birth AND Moderate or severe encephalopathy on clinical examination AND Abnormal background activity of at least 30 minutes' duration or seizures on amplitude integrated electroencephalogram (aEEG)

^a If blood gas is not available or pH is between 7.01 and 7.15 or base deficit is between 10 and 15.9 mmol/L on blood sample obtained within the first hour of birth, two additional criteria are needed: a history of an acute perinatal event (eg, cord prolapse, fetal heart rate decelerations) and either the need for assisted ventilation initiated at birth and continued for 10 minutes or an Apgar score ≤ 5 at 10 minutes after birth.

18% for those who had severe encephalopathy.

Follow-up beyond infancy has been reported for subjects enrolled in the CoolCap trial and the NICHD Whole-Body Cooling trial.^{16,17} Because the follow-up rate at 7 to 8 years of age was only 50% in the CoolCap trial, there were insufficient data to ascertain the long-term risk or benefits of selective head cooling. In the NICHD follow-up study, there was no statistical difference in the composite primary outcome of death or IQ <70 at 6 to 7 years of age between the treated and usual care cohorts ($P = .06$). Hypothermia treatment was associated with a reduction in the secondary outcomes of death (RR, 0.66; 95% CI, 0.45–0.97) and death or cerebral palsy (RR, 0.71; 95% CI, 0.54–0.95).

Observations From Large Clinical Trials

Adverse effects observed with hypothermia were infrequent in the target temperature ranges used in published clinical trials. The most common adverse effects were sinus bradycardia and prolongation of the QT interval on electrocardiogram, both of which are physiologic responses to hypothermia. Reddening or hardening of the skin (systemic hypothermia) and on the scalp (selective head cooling) and subcutaneous fat necrosis occurred rarely. The reported rates of coagulopathy, sepsis, and pneumonia were essentially the same in treated and control infants. When published studies were aggregated in a meta-analysis, the adverse effects of hypothermia included an increase in sinus bradycardia and a significant increase in thrombocytopenia (platelet count <150 000/mm³).¹⁵

Both the TOBY and NICHD trial noted an adverse effect of pyrexia on neurologic outcome among infants allocated to standard care.^{18,19} In both

trials, approximately 30% of the control group had a rectal or esophageal temperature greater than 38°C recorded on at least 1 occasion. The risk for death or disability among infants who had an elevated rectal temperature was increased by threefold in the TOBY trial, whereas in the NICHD trial, the risk for adverse outcome was increased threefold to fourfold, with each degree Celsius increase in the highest quartile of esophageal temperature. It is not known whether the elevated temperatures observed in the 2 trials caused additional brain injury or whether the elevated temperatures were the manifestation of existing hypoxic-ischemic brain injury.

Knowledge Gained From Large Clinical Trials

Approximately 1200 infants were enrolled in the 6 large clinical trials of therapeutic hypothermia. Analyses of aggregate data, as well as data from registries, indicate that moderate hypothermia initiated within 6 hours of birth and continued for 72 hours is a safe and modestly effective neural rescue strategy for infants born at greater than 35 weeks of gestational age who have clinical evidence of moderate or severe neonatal encephalopathy.

Areas of Uncertainty

Because there was little variability among published clinical trials, questions remain regarding the optimal timing for the initiation of cooling and the depth and duration of therapy. There are several ongoing randomized clinical trials that are designed to assess the efficacy of initiating cooling between 6 and 12 hours of age, using a deeper depth of cooling (32°C), or cooling for a longer duration (120 hours) (NCT 01192776, NCT 00614744). In addition, information regarding the safety and efficacy of cooling treatment of encephalopathic infants born

at less than 35 weeks of gestational age is lacking, but preliminary information may be available in the near future (NCT 1793129).

There is also uncertainty regarding the safety and efficacy of initiating cooling before transfer to a center offering therapeutic hypothermia. However, data from the Vermont Oxford Encephalopathic Registry indicate that as many as a third of encephalopathic infants, many of whom were born in other facilities, were not admitted to a neonatal ICU until after 6 hours of age.²⁰ In a study in which active cooling with cool packs was started on arrival of the transport team at the referring center, approximately one-third of the 35 infants had a rectal temperature below 32°C on arrival at the cooling center.²¹ A similar rate of excessive cooling on arrival was noted when passive cooling was used (3 of 18 infants).²² Using a carefully designed protocol for passive cooling at the referral hospital and on transport, Kendall et al noted that 67% of the 39 infants were within target temperature range (33°C–34°C) on arrival at the cooling center, and 11% had a rectal temperature below 32°C.²³ There have been 2 observational studies from the United Kingdom of servo-controlled cooling in the field.^{24,25} Application of this mode of cooling led to significantly less overcooling and greater success in maintaining rectal temperature in the target range when compared with passive cooling.

Clinical Trials of Adjuvant Therapies for Neonatal Encephalopathy

Because the incidence of death and disability remains high after treatment with cooling (approximately 40%), there is an urgent need for additional therapies to further improve outcomes of infants who have acute encephalopathy. Promising neuroprotective agents include antiepileptic drugs, erythropoietin,

melatonin, and xenon. Phase I and II trials of xenon (NCT 00934700, NCT 01545271) and topiramate (NCT 01241019, NCT 01765218) as adjuvant therapy to hypothermia are underway. A phase II study of erythropoietin using doses of 1000 U/kg intravenously in infants undergoing cooling is planned (NCT 01913340) and a phase I and II study of darbepoetin as concurrent therapy with cooling is in progress.²⁶ There is also a phase I–II study assessing the safety and efficacy of clonidine therapy during cooling for neonatal encephalopathy (NCT 01862250).

CONCLUSIONS

1. Medical centers offering hypothermia should be capable of providing comprehensive clinical care, including mechanical ventilation; physiologic (vital signs, temperature) and biochemical (blood gas) monitoring; neuroimaging, including MRI; seizure detection and monitoring with aEEG or EEG; neurologic consultation; and a system in place for monitoring longitudinal neurodevelopmental outcome.
2. Infants offered hypothermia should meet inclusion criteria outlined in published clinical trials (see Table 1). Eligibility criteria include a pH of ≤ 7.0 or a base deficit of ≥ 16 mmol/L in a sample of umbilical cord blood or blood obtained during the first hour after birth,

history of an acute perinatal event, a 10-minute Apgar score of <5 , or assisted ventilation initiated at birth and continued for at least 10 minutes. In addition, a neurologic examination demonstrating moderate to severe encephalopathy is essential. If preferential head cooling is used, an abnormal background activity on either EEG or aEEG also is required.

3. Training programs and infrastructure need to be established and maintained in a highly organized and reproducible manner to ensure patient safety. Each center offering hypothermia therapy needs to develop a written protocol and monitor management and outcomes. Training needs to include awareness and timely identification of infants at risk for encephalopathy and an appropriate assessment of infants who have encephalopathy. Educational endeavors need to involve obstetric care providers; labor, delivery, nursery, and postpartum personnel; and pediatric care providers.
4. Outreach education to community hospitals needs to be implemented. Specific issues include the awareness and timely identification of infants at risk for encephalopathy and prevention of extreme hypothermia and hyperthermia.

5. Cooling infants who are born at less than 35 weeks' gestation or those who have mild encephalopathy, cooling for longer than 72 hours, cooling at a temperature lower than that used in published clinical trials, and the use of adjuvant therapies should only be performed in a research setting and with informed parental consent.

CLINICAL REPORT

Immersion in Water During Labor and Delivery

abstract

FREE

Immersion in water has been suggested as a beneficial alternative for labor, delivery, or both and over the past decades has gained popularity in many parts of the world. Immersion in water during the first stage of labor may be associated with decreased pain or use of anesthesia and decreased duration of labor. However, there is no evidence that immersion in water during the first stage of labor otherwise improves perinatal outcomes, and it should not prevent or inhibit other elements of care. The safety and efficacy of immersion in water during the second stage of labor have not been established, and immersion in water during the second stage of labor has not been associated with maternal or fetal benefit. Given these facts and case reports of rare but serious adverse effects in the newborn, the practice of immersion in the second stage of labor (underwater delivery) should be considered an experimental procedure that only should be performed within the context of an appropriately designed clinical trial with informed consent. Facilities that plan to offer immersion in the first stage of labor need to establish rigorous protocols for candidate selection, maintenance and cleaning of tubs and immersion pools, infection control procedures, monitoring of mothers and fetuses at appropriate intervals while immersed, and immediately and safely moving women out of the tubs if maternal or fetal concerns develop. *Pediatrics* 2014;133:758–761

INTRODUCTION

Immersion in water has been suggested as a beneficial alternative for labor, delivery, or both and over the past decades has gained popularity in many parts of world.^{1–4} Approximately 1% of births in the United Kingdom include at least a period of immersion,⁵ and a 2006 joint statement from the Royal College of Obstetricians and Gynecologists and Royal College of Midwives supported immersion in water during labor for healthy women with uncomplicated pregnancies and stated that to achieve best practice with water birth, it is necessary for organizations to provide systems and structure to support this service.⁶ The prevalence of this practice in the United States is unknown, because such data are not collected as part of

vital statistics. A 2001 survey found that at least 143 US birthing centers offered immersion in water during labor, delivery, or both.⁷ A 2005 commentary by the Committee on Fetus and Newborn of the American Academy of Pediatrics did not endorse underwater birth.⁸ This clinical report reviews the literature concerning the reported risks and benefits of immersion in water during labor and delivery.

EVIDENCE REGARDING IMMERSION IN WATER DURING LABOR AND DELIVERY

Before examining available evidence concerning immersion during childbirth, it is important to recognize the limitations of studies and evidence in this area. Most published articles that recommend underwater births are retrospective reviews of a single center experience, observational studies using historical controls, or personal opinions and testimonials, often in publications that are not peer reviewed.^{1–3,9–11} Also of importance, there are no basic science studies in animals or humans to confirm the physiologic mechanisms proposed to underlie the reported benefits of underwater births.

Other issues, in addition to the nature and design of studies, complicate the interpretation of the published findings, including the absence of a uniform definition of the exposure itself. Often, immersion is referred to as “underwater birth,” but effects and outcomes may be different for immersion during the first stage and second stage of labor. This clinical report, accordingly, avoids the term underwater birth and makes an effort to distinguish data and outcomes related separately to immersion in the first stage and second stage of labor. Not all studies, however, distinguish when in the course of labor and delivery immersion was undertaken.

Outcomes indicating safety or risk in association with immersion at 1 stage may not translate into equivalent outcomes at a different stage of labor; specifically, safety during labor may not translate into safety during delivery. In addition to this important limitation, immersion therapies have varied between studies in the duration of immersion, the depth of the bath or pool, the temperature of the water, and whether or not agitation (jets or whirlpool) was used. In considering the evaluation of outcomes, it is important to note that health care providers involved in providing or studying immersion therapy are not masked to either the treatment or outcomes, and especially in nonrandomized studies, outcomes may be influenced by differences in the environment attending a particular choice of delivery. Finally, most trials of immersion therapy are small, which limits their power to detect rare outcomes.

Randomized controlled trials (RCTs) would be ideal to address many of the aforementioned concerns. A 2009 Cochrane review identified 12 relevant and appropriately designed RCTs of immersion during labor, which involved 3243 women. Nine of these trials involved immersion during the first stage of labor alone (1 of 9 trials compared early versus later immersion during the first stage), 2 trials involved first stage and second stage of labor, and 1 trial involved comparing only the second stage of labor with the controls. Even among these RCTs, however, some of the aforementioned limitations remain, including concerns about power and how the absence of blinding might affect definition of outcomes. The systematic review also noted that most trials have small sample sizes and, thus, a high risk of bias. These factors limit comparison across trials and the reliability and validity of the trial findings.⁵

PROPOSED BENEFITS FROM IMMERSION DURING LABOR AND DELIVERY

There have been claims concerning the positive effects of immersion during labor.^{12–14} Immersion is known to affect maternal cardiovascular physiology as hydrostatic pressure promotes increased venous return and mobilization of extravascular fluid and edema.^{15,16} In part as a result of these effects, proponents of underwater immersion during labor and delivery argue that there are a variety of benefits to such treatment, including a decrease in perinatal pain, a greater sense of well-being and control, and a decreased rate of perineal trauma. Some advocates argue that immersion during labor and delivery decreases maternal stress and stress-associated hormone levels. It could also potentially benefit the newborn infant with a gentler transition from the in utero to ex utero environment.^{1–7}

Individual retrospective analyses and case series argue in support of 1 or more of the benefits listed previously, but among RCTs studying immersion in the first stage of labor that were included in the 2009 Cochrane systematic review,⁵ results were inconsistent. Although many individual RCTs reported no benefit, the combined data indicated that immersion during the first stage of labor was associated with decreased use of epidural, spinal, or paracervical analgesia among those allocated to water immersion compared with controls (478/1254 vs 529/1245; risk ratio [RR] 0.90; 95% confidence interval [CI], 0.82 to 0.99; 6 trials). There was a reduction in duration of the first stage of labor (mean difference –32.4 minutes; 95% CI, –58.7 to –6.13). However, considering each of these effects (particularly the latter), it is difficult to know how factors other than immersion, such as the structure of care (including health

care providers and timing and frequency of examinations) affected outcome. Furthermore, there were no differences in perineal trauma or tears (RR, 1.16; 95% CI, 0.99 to 1.35; 5 trials) or need for either assisted vaginal deliveries (RR, 0.86; 95% CI, 0.71 to 1.05; 7 trials) or cesarean delivery (RR, 1.21; 95% CI, 0.87 to 1.65; 8 trials) between those allocated to the immersion and control arms in the meta-analysis results.

Among the 2 trials that reported outcomes from immersion in the second stage of labor included in this systematic review,⁵ the only difference in maternal outcomes from immersion during the second stage was an improvement in satisfaction among those allocated to immersion in 1 trial. None of the individual trials or the Cochrane systematic review⁵ has reported any benefit to the newborn infant from maternal immersion during labor or delivery.

REPORTED COMPLICATIONS FROM IMMERSION DURING LABOR AND DELIVERY

Individual case reports and case series have noted complications for the mother and the neonate^{17–25} that highlight potential risks from immersion during labor and delivery. Because the denominators are not uniformly reported, the exact incidence of complications is difficult to assess. Some of the reported concerns include higher risk of maternal and neonatal infections, particularly with ruptured membranes; difficulties in neonatal thermoregulation; umbilical cord avulsion and umbilical cord rupture while the newborn infant is lifted or maneuvered through and from the underwater pool at delivery, which leads to serious hemorrhage and shock; respiratory distress and hyponatremia that results from tub-water aspiration (drowning or near drowning); and seizures and perinatal asphyxia.²³

Among this list of complications, given its potential seriousness, the possibility of a neonate aspirating water during birth while immersed has been the focus of understandable concern. Alerdice et al²⁶ summarized case reports of adverse neonatal outcomes, including drownings and near drownings. The case reports included immersion births in hospitals and at home. Subsequently, a study by Byard and Zuccollo reported 4 cases of severe respiratory distress in neonates after water birth, 1 of whom died of overwhelming sepsis from *Pseudomonas aeruginosa*.¹⁹ Although it has been claimed that neonates delivered into the water do not breathe, gasp, or swallow water because of the protective “diving reflex,” studies in experimental animals and a vast body of literature from meconium aspiration syndrome demonstrate that, in compromised fetuses and neonates, the diving reflex is overridden,^{27,28} which leads potentially to gasping and aspiration of the surrounding fluid.

Morbidity and mortality, including respiratory complications, suggested in case series were not seen in the 2009 Cochrane synthesis of RCTs, which concluded that “there is no evidence of increased adverse effects to the fetus/neonate or woman from laboring in water or water birth.”⁵ This conclusion, however, should be tempered by several concerns, including the issue of the power of the sample size to identify rare but potentially serious outcomes. In this regard, in an RCT²⁹ excluded from the Cochrane analysis (because included labors all involved dystocia), 12% of neonates who were delivered in the immersion arm required admission to the NICU, as compared with none in the group delivered without immersion.

SUMMARY

Immersion in water during the first stage of labor may be appealing to

some and may be associated with decreased pain or use of anesthesia and decreased duration of labor; however, there is no evidence that immersion during the first stage of labor otherwise improves perinatal outcomes. Immersion therapy during the first stage of labor should not prevent or inhibit other elements of care, including appropriate maternal and fetal monitoring.

In contrast, the safety and efficacy of immersion in water during the second stage of labor have not been established, and immersion in water during the second stage of labor has not been associated with maternal or fetal benefit. Given these facts and case reports of rare but serious adverse effects in the newborn, the practice of immersion in the second stage of labor (underwater delivery) should be considered an experimental procedure that only should be performed within the context of an appropriately designed clinical trial with informed consent.

Although not the focus of specific trials, facilities that plan to offer immersion in the first stage of labor need to establish rigorous protocols for candidate selection, maintenance and cleaning of tubs and immersion pools, infection control procedures, monitoring of mothers and fetuses at appropriate intervals while immersed, and protocols for moving women from tubs if urgent maternal or fetal concerns develop.

Immunization for *Streptococcus pneumoniae* Infections in High-Risk Children

.....

- *Policy Statement*

POLICY STATEMENT

Immunization for *Streptococcus pneumoniae* Infections in High-Risk Children

abstract

FREE

Routine use of the pneumococcal conjugate vaccines (PCV7 and PCV13), beginning in 2000, has resulted in a dramatic reduction in the incidence of invasive pneumococcal disease (IPD) attributable to serotypes of *Streptococcus pneumoniae* contained in the vaccines. The Advisory Committee on Immunization Practices of the Centers for Disease Control and Prevention and the American Academy of Pediatrics recommend the expanded use of PCV13 in children 6 through 18 years of age with certain conditions that place them at elevated risk of IPD. This statement provides recommendations for the use of PCV13 in children 6 through 18 years. A single dose of PCV13 should be administered to certain children in this age group who are at elevated risk of IPD. Recommendations for the use of PCV13 in healthy children and for pneumococcal polysaccharide vaccine (PPSV23) remain unchanged. *Pediatrics* 2014;134:1230–1233

INTRODUCTION

Invasive disease attributable to *Streptococcus pneumoniae* remains a significant public health problem in children despite widespread use of pneumococcal conjugate vaccines (PCV7 and PCV13; Prevnar; Pfizer, Inc, New York, NY) in US infants 2 through 59 months of age. After the introduction of PCV7 and subsequently PCV13, dramatic decreases in invasive pneumococcal disease (IPD) attributable to vaccine serotypes were noted in young children. However, IPD caused by vaccine serotypes continues to occur in older children with immunodeficiency and certain other high-risk conditions, prompting the need for vaccination recommendations to include these populations.

BACKGROUND AND RATIONALE

S pneumoniae is a leading cause of serious infections, including sepsis and meningitis, and accounts for significant morbidity and mortality in the United States.¹ PCV13 was licensed by the Food and Drug Administration for prevention of IPD and otitis media in infants and young children in February 2010, when it replaced PCV7.² PCV13 is recommended for all children 2 through 59 months of age and for children 60 through 71 months of age with chronic medical conditions (eg, heart disease and diabetes); immunocompromising conditions (eg, HIV infection), including functional or anatomic asplenia, including sickle cell disease; cerebrospinal fluid (CSF) leaks; or cochlear implants (Table 1). For children 6 through 18 years with these same high-risk conditions,

TABLE 1 Underlying Medical Conditions That Are Indications for Pneumococcal Immunization Among Children, by Risk Group^a and Recommended Vaccines

Risk Group	Condition	PCV13		PPSV23	
		Recommended	May Be Considered	1 Dose	Repeat Dose ^b
Immunocompetent children	Chronic heart disease ^c		X	X	
	Chronic lung disease ^d		X	X	
	Diabetes mellitus		X	X	
	CSF leaks	X		X	
	Cochlear implant	X		X	
Children with functional or anatomic asplenia	Sickle cell disease and other hemoglobinopathies	X		X	X
	Congenital or acquired asplenia or splenic dysfunction				
Children with immunocompromising conditions	HIV infection	X		X	X
	Chronic renal failure and nephrotic syndrome	X		X	X
	Diseases associated with treatment with immunosuppressive drugs or radiation therapy,	X		X	X
	including malignant neoplasms, leukemias, lymphomas, and Hodgkin disease; or solid organ transplantation	X		X	X
	Congenital immunodeficiency ^e	X		X	X

^a Centers for Disease Control and Prevention. Licensure of a 13-valent pneumococcal conjugate vaccine (PCV13) and recommendations for use among children. Advisory Committee on Immunization Practices (ACIP). *MMWR Morb Mortal Wkly Rep.* 2010;59(9):258–261.

^b Repeat PPSV23 doses should be 5 y after the first dose.

^c Particularly cyanotic congenital heart disease and cardiac failure.

^d Including asthma, if treated with prolonged high-dose oral corticosteroids.

^e Includes B- (humoral) or T-lymphocyte deficiency; complement deficiencies, particularly C1, C2, C3, and C4 deficiency; and phagocytic disorders (excluding chronic granulomatous disease).

only PPSV23 has been routinely recommended, although there has been a permissive and off-label recommendation by the Advisory Committee on Immunization Practices (ACIP) of the Centers for Disease Control and Prevention (CDC) for use of PCV13.²

In June 2012, the ACIP recommended routine use of PCV13 in addition to PPSV23 for PCV13-naïve adults ≥ 19 years of age with immunocompromising conditions, including functional or anatomic asplenia, including sickle cell disease; CSF leaks; or cochlear implants.³ In June 2013, the ACIP recommended routine use of PCV13 for children 6 through 18 years of age with these same conditions who have not previously received PCV13.⁴ PCV13 should be administered to these children regardless of whether they received PCV7 or PPSV23 previously. Recommendations for PPSV23 use for children remain unchanged.

EVIDENCE TO SUPPORT THE RECOMMENDATION

Pneumococcal conjugate vaccines have decreased the rates of IPD directly in

vaccinated children and indirectly (herd protection) in unvaccinated people.² From 2007 through 2009, the average annual incidence of IPD among children 6 through 18 years of age was 2.6 cases per 100 000 population, with 57% of IPD caused by serotypes included in PCV13 (CDC, Active Bacterial Core surveillance 2007–2009, unpublished data, 2013). Among immunocompromised children 6 through 18 years of age, 49% of IPD was caused by serotypes included in PCV13, and an additional 23% of IPD was caused by serotypes included in PPSV23. Incidence of IPD caused by serotypes included in PCV13 among children 6 through 18 years of age with hematologic malignancies was estimated at 1282 per 100 000 population. Compared with children without this condition, this is a rate ratio (RR) of 822 (95% confidence interval [CI], 687–983). For children with HIV infection, the incidence was 197 per 100 000 population (RR, 122; CI, 94–161), and for children with sickle cell disease, the incidence was 56 (RR, 27; CI, 9–73) (CDC, Active Bacterial Core surveillance 2007–2009, unpublished data, 2013). Children

with certain chronic diseases (eg, cardiac or lung disease) are also known to have elevated risk of IPD but at levels lower than those among children with HIV infection.^{2,5}

PCV13 Efficacy and Safety Among Immunocompromised People

Studies of pneumococcal conjugate vaccines containing similar but fewer antigens have been conducted among people with immunocompromising conditions. From a randomized controlled trial among HIV-infected children 2 through 45 months of age in South Africa, the efficacy of a 9-valent pneumococcal conjugate vaccine (PCV9) was estimated as 65% (CI, 24%–86%) against IPD and 13% (CI, –7%–29%) against radiologically confirmed pneumonia.⁶ Vaccine efficacy of PCV7 against IPD caused by a serotype contained in the vaccine in HIV-infected adults in Malawi was estimated at 74% (CI, 30%–90%).⁷ An observational study conducted in the United States among children ≤ 10 years of age with sickle cell disease estimated vaccine effectiveness against IPD to be 81% (CI, 19%–96%) among those who

received ≥ 1 dose of PCV7.⁸ Although vaccine efficacy and effectiveness have been demonstrated, the duration of protection against IPD remains unknown.

In January 2013, the US Food and Drug Administration approved use of PCV13 in healthy children 6 through 17 years of age for the prevention of IPD caused by serotypes included in the vaccine. Current evidence supports the safety of PCV13 in children with immunocompromising conditions.^{9,10} An open-label, single-arm study of 158 children 6 through 18 years of age with sickle cell disease who previously received PPSV23 demonstrated that 1 dose of PCV13 was safe.⁹ The most common adverse events reported within 7 days of 1 dose included myalgia (74.8%), fatigue (66.1%), and headache (53.6%); less common events included arthralgia (39.8%), fever (26%), vomiting (15.4%), and diarrhea (13.3%). Severe adverse events were reported among 8% of the children and included sickle cell pain crisis (4%), acute chest syndrome (2%), and fever (2%). In a PCV7 efficacy trial among HIV-infected children, the most common adverse events were severe induration, erythema, fever, and restricted leg movement; no serious adverse events were reported.¹⁰

PPSV23 in Immunocompromised Children

PPSV23 contains 12 of the serotypes included in PCV13, plus 11 additional serotypes, which account for 23% of IPD cases among immunocompromised children 6 through 18 years of age (CDC, Active Bacterial Core surveillance 2007–2009, unpublished data, 2013). PPSV23 currently is recommended for children ≥ 2 years of age with elevated risk of IPD.⁴ Given the high burden of IPD caused by serotypes included in PPSV23 but not in PCV13, broader protection should be provided through use of both PCV13 and PPSV23.

POLICY RECOMMENDATIONS

The following recommendation is new and not included in any previous American Academy of Pediatrics (AAP) policy.

Children 6 Through 18 Years of Age With Conditions That Place Them at Highest Risk

A single dose of PCV 13 should be given to children 6 through 18 years of age who have immunocompromising conditions, including HIV infection and functional or anatomic asplenia, including sickle cell disease; CSF leaks; or cochlear implants and who have not previously received PCV13. PCV13 should be administered to these children regardless of whether they received PCV7 or PPSV23 previously. Children in this group who have not previously been immunized with PPSV23 should receive a dose of PPSV23 ≥ 8 weeks after their dose of PCV13. For children in this group who have been previously immunized with PPSV23, a single dose of PCV13 should be given ≥ 8 weeks after the PPSV23 dose.

The following recommendation is unchanged from previous AAP policy.

Children 6 Through 18 Years of Age With Conditions That Place Them at Highest Risk

A second PPSV23 dose is recommended 5 years after the first PPSV23 dose for children with anatomic or functional asplenia, including sickle cell disease, HIV infection, or other immunocompromising conditions. This second dose is not recommended for children with cochlear implants or CSF leaks.

Immunocompetent Children 6 Through 18 Years of Age With Conditions That Place Them at Elevated Risk

Immunocompetent children who have underlying medical conditions that place them at elevated risk for IPD (Table 1)

may also receive PCV13 if they have not previously received PCV13 and regardless of whether they have received PCV7 in the past. If both PCV13 and PPSV23 are used, PCV13 should be administered first, and the administration of PPSV23 should follow at an interval of ≥ 8 weeks. A second dose of PPSV23 is not recommended for this group of children.

Recommendations for the use of PCV13 for children younger than 60 months of age and the use of PPSV23 for children of all ages are unchanged. PCV13 is approved for the Vaccines for Children program through 18 years of age, and the vaccine will be covered by the Vaccine Injury Compensation Program. PPSV23 is not covered by the Vaccine Injury Compensation Program.

FREE

Chronic sleep loss and associated sleepiness and daytime impairments in adolescence are a serious threat to the academic success, health, and safety of our nation's youth and an important public health issue. Understanding the extent and potential short- and long-term repercussions of sleep restriction, as well as the unhealthy sleep practices and environmental factors that contribute to sleep loss in adolescents, is key in setting public policies to mitigate these effects and in counseling patients and families in the clinical setting. This report reviews the current literature on sleep patterns in adolescents, factors contributing to chronic sleep loss (ie, electronic media use, caffeine consumption), and health-related consequences, such as depression, increased obesity risk, and higher rates of drowsy driving accidents. The report also discusses the potential role of later school start times as a means of reducing adolescent sleepiness. *Pediatrics* 2014;134:e921–e932

INTRODUCTION

Since the publication of the American Academy of Pediatrics technical report on excessive sleepiness in adolescents in 2005,¹ there have been a considerable number of articles published pertaining to sleep. These articles expand on many of the topics raised in the original report and add a number of new important health issues not previously or minimally discussed (ie, short sleep and its association with obesity, caffeine/stimulant use). The previous technical report provided an overview of the profound changes in sleep–wake regulation and circadian biology occurring during adolescence, outlined factors (ie, parental influence, school start times) contributing to insufficient sleep in adolescents, and summarized consequences such as negative impacts on mood, attention, and school performance. It also focused in particular on clinical sleep disorders such as insomnia, narcolepsy, and restless legs syndrome contributing to daytime sleepiness in adolescents. The new material in the present report adds to what is known about the extent of sleep restriction in the adolescent population and reinforces the importance of recognizing insufficient sleep both as a key public health issue and one that is immediately relevant to pediatric practice.

The focus of this updated technical report is on insufficient sleep, specifically as a consequence of voluntary sleep restriction. It should

be noted that such terms as insufficient sleep, inadequate sleep, short sleep duration, sleep loss, and sleep restriction are used interchangeably and as generic descriptive terms only and do not imply specific amounts but rather “less sleep than needed.”

Insufficient sleep in adolescents was recognized as a serious health risk in 2010 in a jointly sponsored American Medical Association/American Academy of Sleep Medicine resolution acknowledging the problem.² Furthermore, objectives for Sleep Health, a new topic in Healthy People 2020,³ specifically includes reducing adolescent sleep loss: “SH-3: Increase the proportion of students in grades 9 through 12 who get sufficient sleep” (defined as ≥ 8 hours). A second focus of the present report is on unhealthy sleep behaviors (ie, poor “sleep hygiene”) in teenagers, including irregular sleep–wake patterns, electronic media use in the bedroom, and excessive caffeine use. A third focus is on the myriad of potential consequences of inadequate sleep in adolescents, including depression/suicidal ideation, obesity, car crashes attributable to drowsiness, and poor academic performance.

EPIDEMIOLOGIC STUDIES OF SLEEPING ADOLESCENTS

Epidemiologic studies of sleep typically rely on self- or parent-reported questionnaire data to document adolescent sleep patterns and the factors affecting them. The key advantage of this method is the ease of assessment of large sample sizes. As a result, epidemiologic studies can determine sleep patterns across the full adolescent age range with less potential sampling bias than smaller case-control studies. Consistent with other methodologic approaches, the consensus finding across epidemiologic studies is that both younger^{4–6} and older^{4,7–11} adolescents are not getting enough sleep. It is important to

note that studies comparing self-reported sleep duration with objectively measured sleep amounts (ie, with actigraphy) suggest that self-reports of sleep often overestimate actual sleep duration, signifying that the problem of chronic sleep loss in adolescents may be even greater than the data indicate.¹² US-based^{4,13} and international studies^{5,6,14} revealed that as students get older, sleep durations decline. The National Sleep Foundation Sleep in America Poll⁴ found that by the 12th grade, 75% of students self-reported sleep durations of less than 8 hours of sleep per night compared with 16% of sixth graders. Furthermore, although 30% to 41% of sixth through eighth graders were getting 9 or more hours of sleep, only 3% of 12th graders reported doing so. Adolescents often attempt to address the accumulated weekday sleep debt during the weekend, when oversleep (the difference between weekday and weekend sleep durations) of up to 2 or more hours is commonly reported.^{4,7,8,15,16}

Comparisons with other countries show similar patterns of decreased sleep durations with increasing age among adolescents. For example, in Northern Taiwan,⁵ Germany,¹⁴ and India,¹⁷ average sleep duration dropped to below 8 hours for high school–aged students. The most precipitous drop was reported in 2005 for more than 1400 South Korean adolescents, for whom the average duration of sleep was 4.9 hours.⁶ In general, studies have demonstrated similar weekend sleep durations across countries, but weekday sleep durations tend to vary greatly.^{5,9} In contrast, Australian adolescents seem to do comparatively well, with students 17 years and older reporting average sleep durations between 8.5 and 9.1 hours.¹⁸ The difference between weeknight and weekend sleep durations also was not large, with weekend durations reported at 9.3 hours. Interestingly, although data on school start times in the Australian

study were not presented, the average reported wake times on school days was 7:00 AM or later, suggesting that the schools these students attended did not start before 8:00 AM.

A number of studies have indicated that sleep health disparities exist and that adults,¹⁹ children, and adolescents^{20–22} from families with low income or of racial or ethnic minorities may be at even greater risk of poor-quality and insufficient sleep. For example, in a recent study of middle school students, appropriate timing and consistency of both weeknight and weekend sleep schedules were inversely correlated with low socioeconomic status and specific household/neighborhood variables (eg, overcrowding, noise levels, safety concerns).²³ This relationship may have important health implications. For example, a recent study suggested that less sleep was a predictor of obesity risk in African-American adolescents but not in white adolescents.²⁴ “Missed” sleep was also reported to be an important factor in asthma morbidity, especially in Latino children.²⁵ However, higher socioeconomic status is not necessarily protective because studies have also shown that youth from households with higher socioeconomic status have shorter sleep durations.^{16,26}

For older adolescents, additional environmental factors, such as after-school employment,¹⁶ striving for good grades,^{5,6,12} socializing,^{27,28} participation in sports and other extracurricular activities, and lack of parental monitoring or rules about bedtimes, can further interfere with sleep durations.^{6,29,30} School start times are reviewed later in the present report.

In summary, short sleep durations, coupled with evidence of daytime sleepiness (eg, increased self-reported sleepiness ratings,^{5,6,11,31} daytime napping,^{5,14,26} weekend oversleeping,^{6,10,14,32} need for assistance in waking⁶), as well as increased use of fatigue countermeasures

(eg, excessive caffeine consumption^{4,5,15}), all indicate that adolescents are sleeping fewer hours than they need. The clear and consistent message is that middle and high school students are not getting enough sleep and that this issue is a chronic problem worldwide. In addition, the health and behavioral outcomes linked to restricted sleep, as further detailed in the following sections, are alarming. These outcomes include increased risk of car crashes,^{4,33} delinquent behaviors,²⁷ depression,^{8,10,34} and psychological stress.³⁵

FACTORS CONTRIBUTING TO INSUFFICIENT SLEEP IN ADOLESCENTS

Influence of Biological Processes on Adolescent Sleep

The association of early adolescent development/pubertal onset and a more evening-type circadian phase preference (ie, preferred timing of sleep and wake as well as daytime activities) has been documented since the 1990s.³⁶ The behavioral result of this biological process is most clear in the timing of sleep, particularly for weekends. For example, Roenneberg et al³⁷ measured the midpoint of weekend sleep in European schoolchildren and revealed a marked linear delay of 2 (girls) to 3 (boys) hours across the second decade, roughly 12 to 18 minutes later with each year of age. The reversal of this delayed weekend sleep pattern may be a “biological marker for the end of adolescence.”

Recent data have indicated that another process involved in regulating sleep timing seems to be altered to favor late nights across adolescent development. This process, called sleep–wake homeostasis, can be thought of as the system that accounts for greater pressure to sleep as one stays awake longer. Data collected with 2 different paradigms to estimate the rate of buildup of sleep pressure in prepubertal versus postpubertal adolescents indicate that

more mature adolescents accumulate this sleep pressure at a slower rate.^{38,39}

Maturational changes to these 2 bioregulatory processes begin in adolescents as young as middle school and present a major challenge for young people to fall asleep in the early evening and to wake refreshed/restored in the early morning to attend school. The most prominent factors in this regard are evening and nighttime screen use and social networking, both of which have increased markedly in the 21st century.⁴⁰ Going to bed later and waking later on weekends than on weekdays reflects the biology of circadian rhythm and is also a response to insufficient weekday sleep. Later sleep timing and catch-up sleep on the weekends further delay the signal for the biological night (ie, melatonin production) and dissipate residual sleep pressure.⁴¹ In summary, the combination of biologically driven processes with modern lifestyles and social obligations minimize the opportunities for adolescents to obtain adequate sleep.

Electronic Media and Sleep

Today's adolescents and young adults have grown up in an electronic age. According to the National Sleep Foundation's 2006 Sleep in America Poll, almost all adolescents had at least 1 media electronic device in their bedroom.⁴ Among the devices reported were televisions (57%), music players (90%), video game consoles (43%), computers (28%), and phones (64%). A more rigorous study of subjects recruited from a pediatric office in a Philadelphia suburb showed that of the 100 adolescents ranging in age from 12 to 18 years, two-thirds had a television in their bedroom, almost one-third had a computer, almost 80% had a digital music player, and 90% had a cellular phone in their bedroom.⁴² The teenagers engaged simultaneously

in an average of 4 electronic activities after 9:00 PM.

It is not surprising that several studies in adolescents have demonstrated that electronic exposure in the evening potentially disrupts sleep. The use of multiple electronic devices at the same time has been associated with less sleep at night and a greater degree of sleepiness during the daytime.^{4,15,31,42,43} Having a television in the bedroom (or even out of the bedroom) has been associated with later bedtimes on weekdays, longer sleep latencies, shorter total sleep times, later wakeup times on the weekends, and more daytime sleepiness in adolescents.^{44–46} In the Children in the Community Study in 1976,⁴⁷ adolescents who were watching 3 or more hours of television not only experienced difficulty falling asleep and frequent awakenings but also had a risk of having difficulties with their sleep later in adolescence and young adulthood. The use of computers before bedtime has also been shown to have the same effect, and this finding has been demonstrated in a wide range of countries and cultures.^{45,46,48–51}

Engaging in a greater number and range of sleep-interfering activities before going to bed has also been associated with less nocturnal sleep and more daytime sleepiness in adolescents.⁴⁵ Several mechanisms have been postulated about how media disrupts sleep.⁴⁰ One is that the use of media directly displaces sleep; an adolescent or young adult may simply stay up later enjoying whatever media he or she is using. In addition, electronic media allow for greater interaction between friends. Early data suggested that peer-to-peer interaction did not have a major influence on school-night bedtime but rather had a more significant influence on a teenager's sleep on weekends.⁵² These findings may no

longer hold now that there are enhanced ways for adolescents to communicate electronically. Calamaro et al⁴² found that after 9:00 PM, 34% of adolescents in the study sample were text messaging, 44% were talking on the phone, 55% were online, and 24% were playing computer games. In another study of Belgian teenagers, 62% of the subjects used their phones after the lights were turned off, and phone use at this time was associated with increased daytime tiredness the next day.⁵³

Another possible mechanism for the detrimental effect of electronics use on sleep is that the light produced by electronic devices may disrupt circadian rhythms by suppressing melatonin, resulting in the inability to fall asleep at a reasonable time.⁴⁰ Recent studies have demonstrated that exposure to relatively low-intensity light can alter circadian rhythms^{54,55} and suppress nocturnal melatonin secretion.⁵⁶

Finally, media use may cause increased sleep-disrupting mental, emotional, and physiologic arousal.⁴⁰ One study found that subjective sleepiness was lower, sleep latency was longer, and rapid eye movement (REM) sleep was shorter in subjects after playing video shooting games, independent of the brightness of the screen used.⁵⁶ Another study that compared playing an interactive computer game with watching a movie on television in the evening⁵¹ found a decline in verbal memory performance, prolonged sleep latency, and an increase in light sleep in the computer game cohort.

School Start Times

As has been described elsewhere in the present report, a multitude of changes occur over the course of adolescence that can affect the quality and quantity of sleep in adolescents and young adults. One of the most salient and arguably most malleable is that of school start times, a systemic

countermeasure. There are clearly a number of practical implications and/or challenges that schools might face when considering altering school start times, such as changes in athletic schedules, effects on after-school activities, and transportation issues.⁵⁷ Despite these hurdles, a small yet increasing number of school districts over the last 15 years have responded to research reports regarding the prevalence of inadequate sleep among middle and high school students by delaying school start times. Research on the effects of delaying the start times of middle and high schools for adolescents' sleep and daytime functioning is discussed in this section, and a more detailed discussion is available in the American Academy of Pediatrics policy statement on school start times.⁵⁸

In one of the first studies to assess the effect of school start times on adolescents,⁵⁹ a 65-minute earlier school start time in the transition from grade 9 to grade 10 resulted in fewer than one-half of 10th graders obtaining an average of 7 hours or more of sleep on school nights and physiologic levels of daytime sleepiness ordinarily seen in patients with narcolepsy. A large prospective longitudinal study of delays in school start times in both an urban and a suburban school district found improvements in attendance rates and an increase in the percentage of high school students continuously enrolled in the district or the same school, although grades did not show a statistically significant improvement.⁶⁰ Similar to what has been reported in subsequent studies,⁵⁵ bedtimes did not change with the delay in start times, but morning wake times were significantly later, resulting in the students obtaining nearly 1 hour more of sleep on school nights. Other studies have also reported increases in sleep duration

and decreased daytime sleepiness associated with delayed school start times,⁶¹ as well as increased satisfaction with sleep and motivation and significant declines in self-reported depressed mood, health center visits for fatigue-related complaints, and first-period tardiness.⁶²

Research on the effects of early versus delayed school start times for young adolescents has resulted in strikingly similar findings. Students at later-starting middle schools report later rise times, more total sleep on school nights, less daytime sleepiness, less tardiness, fewer attention/concentration difficulties, and better academic performance compared with middle school students at earlier-starting schools.^{63,64} In addition, middle school students with a delayed start time of 1 hour for just 1 week performed better than the earlier-starting comparison group on tests requiring attention.⁶⁵ Undoubtedly, delaying the start of middle school allows early adolescents, similar to their older high school-aged peers, to obtain sufficient sleep and to perform better in school.

Danner and Phillips⁵³ demonstrated that delaying school start times in 1 community in Kentucky decreased the average crash rate for teenaged drivers by 16.5%, while the state as a whole increased by 7.8% in the same time period. In another recent study conducted in 2 adjacent, demographically similar cities, there were significantly increased teenaged (16- to 18-year-olds) crash rates over a 2-year period in the city with earlier high school start times.⁶⁶

Taken together, it is clear that when middle and high schools (schools designed for adolescents) institute the countermeasure of delaying the start time of school, students obtain more sleep and there are associated improvements in behaviors pertinent to academic success (attendance and school performance) and safety.

Caffeine

Use of caffeine has been understudied in adolescents and children; however, current research has raised important questions regarding the complex interrelationship between caffeine use and sleep patterns during this developmental period.^{67–70}

Similar to studies of adult caffeine use, higher caffeine intake as early as 12 years of age is associated with shorter sleep duration, increased sleep onset latency, increased wake time after sleep onset, and increased daytime sleepiness.^{68,69,71} High school students who report a moderate to high intake of caffeine versus very low intake were nearly 2 times more likely to have difficulty sleeping and to report morning sleepiness.⁷¹ High and regular caffeine users seem to develop a cycle in which disrupted sleep attributable to caffeine use leads to sleepiness, which then leads them to increase their caffeine consumption.⁷² Moreover, caffeine reduces the percentage of time spent in slow-wave or “deep” sleep in a dose-related manner and alters the temporal organization of REM/non-REM sleep.^{70,72,73} This outcome is particularly important because of the critical role that both slow-wave sleep and REM sleep play in learning and memory consolidation.

Researchers are beginning to examine adolescents’ expectancies regarding caffeine use. Reported expectancies for caffeine users were for energy and mood enhancement and to counteract the effects of sleep disturbances. Other studies have found that adolescents report using energy drinks for the energy boost or “buzz” and that these beverages make them “feel more energetic.”⁷⁴ In comparing different types of users, “mixed” caffeine product users (ie, soda, coffee, energy drinks) reported higher levels of withdrawal and/or dependence, energy and mood enhancement, appetite suppression, and performance enhancement expectancies

than either the high-soda or low-caffeine use groups. A higher percentage of mixed users compared with high-soda users reported that the reasons for their caffeine use were related to getting through the day, experimentation, and recreation.⁶⁸

Regardless of the reasons adolescents use caffeinated substances, there are clear consequences. Adolescents experience tolerance and withdrawal symptoms; however, in general, caffeine dependence in adolescents is poorly understood.^{75,76} Female high school students were more likely to report withdrawal/dependence caffeine expectancies as well as appetite suppression expectancies compared with their male peers.⁶⁸ Although adolescents may consume excessive caffeine in an attempt to mitigate daytime sleepiness, this action not only further compromises the quality and quantity of sleep, but high caffeine users may also be at risk for other substance use and/or abuse as well as other risk-taking behaviors.^{68,75,77–79} Consumption of caffeine is linked to nicotine use in adolescents,⁸⁰ which in turn may further disrupt sleep⁸¹ and perpetuate the cycle of sleep fragmentation/daytime sleepiness coupled with stimulant use. Not surprisingly, increased caffeine use frequently coexists with other behaviors that negatively affect sleep, such as adolescents’ late-night, multifaceted technology use. For example, a recent study⁴² found that high school-aged adolescents who reported the highest levels of multitasking with media-related electronic products also consumed the most caffeine.

The correlation between caffeine consumption and daytime sleepiness is, in turn, inversely correlated with academic achievement. For example, 1 study of over 7000 adolescents reported that a significant proportion of the variance that occurs in academic achievement

was found to be attributable to caffeine use.⁸² The authors further postulated that daytime sleepiness might be an important mediator of the negative impact of not only caffeine but also alcohol use and cigarette smoking on academic success. Caffeine use may also serve as an affect modulator, particularly when it comes to adolescents with excessive daytime sleepiness or insufficient sleep. For example, studies have suggested that adolescents may use caffeine as a means of regulating mood and/or helping to alleviate depression.^{75,83}

Undoubtedly, there is growing evidence that caffeine use is increasing among adolescents, with negative implications for sleep and other behaviors. Significant questions, however, remain regarding the direction of this complex relationship. Are adolescents turning to caffeine because of insufficient and inconsistent sleep patterns, or does increased caffeine use exacerbate sleep problems for developing adolescents? These findings document the need for more extensive health education about caffeine use during adolescence. Furthermore, with the dramatic and potentially dangerous rise in the consumption of energy drinks in combination with alcohol (particularly on college campuses), researchers and physicians need to carefully investigate the implications for adolescents across the developmental spectrum.⁸⁴

Other Factors Affecting Sleep in Adolescents

A number of other factors have been related to reduced sleep durations across the adolescent age range, such as chronic medical illnesses, mental health issues (ie, anxiety/stress), and prescribed psychotropic medications.^{10,15} Chronic respiratory illnesses, such as asthma, and pain conditions, such as migraines, may contribute to truncated and disrupted sleep. Although obesity

does not necessarily lead to poor sleep per se, it is an increasingly important risk factor for obstructive sleep apnea in adolescents, which in turn results in poor-quality sleep and daytime consequences. Moreover, although the evidence is still largely anecdotal, the use of stimulants (particularly those typically prescribed for the treatment of attention-deficit/hyperactivity disorder) as a “countermeasure” to sleepiness and/or as academic “performance enhancers” seems to be an increasingly common phenomenon across college campuses.^{85,86} Future investigations need to assess the extent and context of “diversion” of legitimately prescribed stimulant medications as well as the use and abuse of increasingly diverse alternative sources of caffeine (eg, caffeinated alcoholic beverages, candy, foodstuffs). Finally, it should also be noted that both over-the-counter (ie, diphenhydramine) and prescription (ie, zolpidem) medications taken by adolescents to induce sleep may result in residual daytime sleepiness and that commonly used medications (eg, decongestants) and prescription drugs (eg, activating antidepressants [eg, fluoxetine], stimulant medication for attention-deficit/hyperactivity disorder) may also result in disrupted sleep and consequent daytime sleepiness in adolescents.

CONSEQUENCES OF INSUFFICIENT SLEEP

It is important to recognize that the causes and consequences of chronic sleep loss in adolescents are often closely intertwined in complex ways, further exacerbating the situation. For example, alcohol consumption can lead to insufficient and poor-quality sleep and subsequent daytime sleepiness.^{10,32,87} In turn, chronic sleep loss has been linked to an increased risk of alcohol and drug use.^{14,28,34} Similarly, compensatory oversleep behavior on weekends provides some temporary relief from sleepiness generated by insufficient

sleep on weekdays, but it also leads to disrupted sleep–wake cycles, exacerbation of the normal adolescent circadian phase delay, and perpetuation of compromised weekday alertness. Moreover, consequences such as poor judgment, lack of motivation, and inattention and affective dysregulation resulting from sleep loss, as well as the effect of insufficient sleep on decision-making skills,⁸⁸ further compound the potential negative effects in adolescents. In particular, higher level cognitive “executive functions,” for which adolescence is a critical period of evolution, are selectively affected by sleep loss.⁸⁹

Sleep Loss and Depression, Mood Disturbances, and Suicidal Ideation

It has long been recognized that mood disorders (especially major depressive disorder) in clinical samples of adults exhibit a bidirectional relationship with sleep disturbances, and the presence of sleep problems has been shown to both increase the relative risk of developing depression⁹⁰ and to be a predictor of relapse.^{91,92} Similar findings have emerged in the child and adolescent population, particularly with regard to an association between insomnia (difficulty initiating and/or maintaining sleep) and clinically diagnosed depression.⁹³ Recent studies have shown that addressing insomnia will greatly improve treatment of depression. Although studies examining sleep architecture in depressed adolescents⁹⁴ have not consistently replicated differences in polysomnographic findings in depressed adults (ie, increased REM sleep, decreased REM onset latency), there may be other sleep electroencephalographic markers, such as sleep spindle activity and cyclic alternating patterns,⁹⁵ that have more relevance for the adolescent population.

Sleep debt in college students has been shown to be associated with

a higher risk of reporting depressive symptoms.⁹⁶ Similarly, in high school students, shorter school-night total sleep time has been associated with both daytime sleepiness and depressive symptoms,⁹⁷ whereas increased risk-taking behaviors were associated with irregular sleep patterns and self-reported sleep problems rather than sleep loss. These outcomes are similar to the findings of a large longitudinal adolescent health study in which symptoms of possible insomnia (ie, trouble sleeping, morning tiredness) predicted risk behaviors (eg, drinking and driving, smoking, delinquency) after controlling for depression symptoms.^{97,98}

There is evidence that other sleep-related parameters may also have a significant effect on mood; for example, adolescent self-reported sleep variables (including trouble sleeping, tiredness, nightmares, and being a long sleeper) have been found to be significantly associated with psychological symptoms, including anxiety/depression, and withdrawal.⁹⁹ Circadian factors may also play a role in mood regulation; increased self-reported “eveningness,” a marker of circadian phase delay, has also been associated with depression and lower behavior activation/positive affect.¹⁰⁰

A number of recent studies have focused on the possible relationship between sleep and suicidal ideation.^{101,102} Sleeping less than 8 hours at night seems to be associated with an almost threefold increased risk of suicide attempts after controlling for a number of confounding variables.¹⁰¹ Not only do adolescents with insufficient sleep have an increased risk of suicidal ideation, but the risk may be similarly increased in adolescents whose parents also have insufficient sleep, raising some interesting questions about multigenerational environmental and/or genetic factors.¹⁰³ A

similar relationship has been found in middle and high school students; adolescents with parental-set bedtimes of midnight or later are significantly more likely to suffer from depression and to have suicidal ideation compared with adolescents with parental-set bedtimes of 10:00 PM or earlier. Earlier parental-set bedtimes, therefore, could potentially be protective against adolescent depression and suicidal ideation. Finally, both decreased (≤ 5 hours) or increased (≥ 10 hours) total sleep times may put adolescents at a significantly higher risk of suicidality compared with a total sleep time of 8 hours.¹⁰⁴ However, increased risk of the most severe forms of suicidality (attempt requiring treatment) seems to be associated with significantly shorter sleep duration (total sleep time ≤ 4 hours).

In summary, sleep has an important influence on mood and the development of depressive symptoms in adolescents. Although insufficient sleep and daytime sleepiness seem to have the most robust relationship with mood dysregulation, poor-quality sleep and irregular sleep patterns are also associated with depressed mood. Importantly, from a clinical standpoint, improvements in sleep may lead to improvements in mental health functioning (and vice versa). The association between sleep loss and increased suicidality in adolescents is particularly troubling and is clearly important for pediatricians to recognize.

Insufficient Sleep and Obesity Risk

A considerable body of evidence now links short sleep duration in both adults and children with an increased risk of obesity, an association that obviously has long-range health implications. With regard to mechanisms, experimental studies of sleep restriction in healthy adult volunteers have shown that there are alterations in

metabolic profiles (eg, insulin, ghrelin, leptin, cortisol) associated with sleep loss, which result in insulin resistance, increased sympathetic nervous system activity, and increased hunger and decreased satiety.¹⁰⁵ As a result, sleep-restricted subjects consume more calories, exercise less, and consume a higher percentage of calories from fat.^{106–109}

In 1 earlier study, it was estimated that for each hour sleep lost, the odds of being obese increased in adolescents by 80%.¹¹⁰ Furthermore, there is evidence of a “dose–response” inverse relationship between sleep and weight,¹¹¹ with odds ratios of overweight increasing with decreasing sleep duration (< 5 hours, 5–6 hours, 6–7 hours, and 7–8 hours compared with students sleeping > 8 hours). The increased risk of obesity associated with insufficient sleep seems to be equivalent to or higher than the risk associated with other factors strongly correlated with weight, such as parental obesity and television viewing.¹¹²

Early sleep patterns may influence BMI in adolescents and young adults as well. Longitudinal data suggest that children who sleep less, have later bedtimes, or get up earlier subsequently have higher BMIs and are more likely to be overweight, even after controlling for baseline BMI.¹¹³ This association may be established early in life; for example, an increased BMI and high prevalence of obesity in young adults was found in individuals whose mothers had reported sleeping problems (“irregular” or “troubled” sleeping) at ages 2 to 4 years (although sleep duration was not specified) compared with those who had not had sleeping problems.¹¹⁴

Although the underlying potential mechanisms for the relationship between sleep and weight in adolescents have yet to be elucidated, metabolic alterations associated with sleep loss similar to those observed in adults are

likely to play an important role. In particular, perturbations in the levels of neurohormones known to be associated with hunger and satiety (eg, adiponectin, ghrelin) as well as increased insulin resistance (as measured by the homeostatic model assessment [HOMA]) have been demonstrated in adolescents sleeping < 5 hours per day.¹¹⁵ These “short sleepers” were also found to have a higher percentage of carbohydrate intake according to a dietary questionnaire.¹¹⁶ Similarly, older adolescents sleeping less than 8 hours have been shown to consume a higher proportion of calories from fats, and shorter sleep duration is also associated with increased odds of consuming a higher percentage of daily caloric intake from snacks.¹¹⁷ Importantly, these metabolic perturbations also increase the risk of development of type 2 diabetes in these obese adolescents.^{118,119} Finally, it should be noted that the relationship between short sleep duration and obesity may be further complicated by the presence of obstructive sleep apnea. Not only is obesity emerging as an increasingly important risk factor for sleep-disordered breathing in children,¹²⁰ but obstructive sleep apnea may further exacerbate the inflammatory and metabolic consequences of both obesity and chronic sleep loss.^{7,121–123} Some evidence also suggests there may be gender differences in the strength of the association between obesity and sleep duration, with adolescent boys seeming to be at higher risk compared with girls in both cross-sectional and longitudinal studies using large data sets.¹²⁴ However, not all studies have identified gender differences; in 1 study of junior high school students, short sleep duration was significantly associated with overweight in girls only.¹²⁵

Finally, it should be noted that not all studies have found an inverse

relationship between sleep duration and obesity in adolescents.¹²⁶ It has been postulated that some of these discrepancies may be attributable to measurement issues; in a nationally representative sample of adolescents that included 2 different measures of sleep duration (24-hour time diaries and self-reported “usual” sleep hours), self-reported sleep duration and time-diary sleep were only weakly correlated with each other, and only self-reported sleep hours were inversely associated with overweight.¹²⁷

In summary, despite a number of methodologic limitations, the body of evidence from studies assessing the relationship between short sleep and increased overweight/obesity risk in adolescents is both compelling and potentially far-reaching in its public health implications. More research is urgently needed to identify specific metabolic, inflammatory, and hormonal mechanisms as well as the interactions among sleepiness and activity levels, mood, cognition, and behavioral responses in this complex equation. Moving forward, both community-based obesity prevention programs, such as “Let’s Move” (<http://www.letsmove.gov>), and clinical treatment programs for overweight and obese teenagers should include consideration of sleep as an important variable in the relative success or failure of these interventions.

Drowsy Driving in Adolescents

It is now well recognized that daytime sleepiness and fatigue are associated with an increased rate of motor vehicle crashes.^{128–131} The fact that sleepiness could be a major factor in individuals without known sleep disorders was not universally accepted until the landmark paper¹³² by Pack et al in 1995. This group reviewed crash

reports from the state of North Carolina between 1990 and 1992 in which the driver was judged to have fallen asleep behind the wheel. In the 85% of crashes in which intoxication was not thought to be a contributing factor, the majority (55%) occurred in individuals 25 years or younger. Crashes in this younger age range generally occur at night, unlike crashes with older adults, which typically occur during the mid-afternoon,^{133,134} and tend to occur predominantly when the drowsy driver is alone.^{135–137} In addition, young male drivers are more likely to be involved in sleep-related crashes than are young female drivers.^{132,134,136}

Sleepiness while driving is a common complaint among adolescents¹³⁶ and college students.¹³⁷ In a study of high school students with driver’s licenses, one-fifth reported poor-quality sleep, almost two-thirds complained of daytime sleepiness, 40% reported having sleepiness while driving, and 11% reported having had an automobile crash in which sleepiness was the main cause. Being sleepy behind the wheel and poor-quality sleep at night also seem to increase the risk of having an automobile crash in college students.

Countermeasures may potentially help prevent traffic accidents in this age range. Avoidance of driving when sleep deprived and not drinking alcohol before getting behind the wheel are obvious solutions. Other countermeasures that have some empiric support in adults and may be effective in adolescents include planned napping.^{138,139}

CONCLUSIONS

Adolescent sleep loss poses a serious risk to the physical and emotional health, academic success, and safety of our nation’s youth. The prevalence and effects of insufficient sleep may

be further magnified in high-risk adolescents. Pediatricians have the opportunity to make significant inroads into addressing the health risk that sleep loss presents through screening and health education efforts. Many of the factors that have been shown to contribute significantly to the current “epidemic” of insufficient sleep in teenagers, such as electronic media use, caffeine consumption, and early school start times, are potentially modifiable and, as such, are important intervention points in anticipatory guidance in the clinical setting. On the local and national levels, pediatricians need to advocate for educational, administrative, and health policies that promote healthy sleep and reduce the risk factors for sleep loss in adolescents.

TECHNICAL REPORT

Interferon- γ Release Assays for Diagnosis of Tuberculosis Infection and Disease in Children

Jeffrey R. Starke, MD, FAAP and COMMITTEE ON INFECTIOUS DISEASES

KEY WORDS

bacille Calmette-Guérin, interferon- γ release assay, tuberculin skin test, tuberculosis

ABBREVIATIONS

BCG—bacille Calmette-Guérin
 ELISA—enzyme-linked immunosorbent assay
 ELISPOT—enzyme-linked immunosorbent spot
 IGRA—interferon- γ release assay
 INF- γ —interferon- γ
 LTBI—latent tuberculosis infection
 NTM—nontuberculous mycobacteria
 PPD—purified protein derivative
 QFT—QuantIFERON-TB Gold In-Tube assay
 TB—tuberculosis
 T-SPOT—T-SPOT.TB assay
 TST—tuberculin skin test

Tuberculosis (TB) remains an important problem among children in the United States and throughout the world. Although diagnosis and treatment of infection with *Mycobacterium tuberculosis* (also referred to as latent tuberculosis infection [LTBI] or TB infection) remain the lynchpins of TB prevention, there is no diagnostic reference standard for LTBI. The tuberculin skin test (TST) has many limitations, including difficulty in administration and interpretation, the need for a return visit by the patient, and false-positive results caused by significant cross-reaction with *Mycobacterium bovis*-bacille Calmette-Guérin (BCG) vaccines and many nontuberculous mycobacteria. Interferon- γ release assays (IGRAs) are blood tests that measure ex vivo T-lymphocyte release of interferon- γ after stimulation by antigens specific for *M tuberculosis*. Because these antigens are not found on *M bovis*-BCG or most nontuberculous mycobacteria, IGRAs are more specific tests than the TST, yielding fewer false-positive results. However, IGRAs have little advantage over the TST in sensitivity, and both methods have reduced sensitivity in immunocompromised children, including children with severe TB disease. Both methods have a higher positive predictive value when applied to children with risk factors for LTBI. Unfortunately, neither method distinguishes between TB infection and TB disease. The objective of this technical report is to review what IGRAs are most useful for: (1) increasing test specificity in children who have received a BCG vaccine and may have a false-positive TST result; (2) using with the TST to increase sensitivity for finding LTBI in patients at high risk of developing progression from LTBI to disease; and (3) helping to diagnose TB disease. *Pediatrics* 2014;134:e1763–e1773

INTRODUCTION

Tuberculosis (TB) remains an important disease in the United States and throughout the world. Of the almost 9 million annual cases of TB globally, approximately 10 000 cases occur in the United States.¹ Of the 2660 children and adolescents younger than 18 years with TB disease reported in the United States from 2008 to 2010, 31% were born in other countries.² Among the US-born pediatric patients, 66% had at least 1 foreign-born parent, and 75% of all the pediatric patients had some international connection through family or residence history. Although 52% of these cases occurred in children ages 13 to 17 years,

infants and young children have the highest rate of TB infection progressing to TB disease rapidly after exposure (ie, within a few weeks to several months). Children who immigrated to the United States from countries with high TB burden often received no testing for latent tuberculosis infection (LTBI), expanding the pool of infected children in the United States. Some of these children developed TB disease or were evaluated and treated for LTBI after immigration, but many have untreated LTBI and are at risk for developing TB disease later in life. In addition, many US-born children who have been infected with *Mycobacterium tuberculosis* within the United States or abroad have gone undetected.

In most children and adolescents, initial infection with *M tuberculosis* is eliminated or contained by host defenses, the infection becomes “latent,” and the person remains asymptomatic. However, latent bacilli may remain viable and become active again to cause TB disease. Treatment of LTBI substantially reduces the risk of developing TB disease in both the immediate and distant future.³ Therefore, the goal of testing for LTBI is to identify those individuals who are at increased risk of developing TB disease and will benefit the most from treatment. In the pediatric population, infants and very young children and adolescents are at higher risk of progressing to TB disease than are primary school-aged children. The risk of progression in infants younger than 12 months is 40%; it is decreased to 25% in children 1 to 2 years of age and is 10% to 15% in older children and adolescents. Epidemiologic factors also define risk: children who were born and lived in or have traveled to an area of the world with a high prevalence of TB and those who have had a household or family member with TB disease or LTBI are at higher risk for LTBI than the general population. As

a result, selective testing for LTBI of children on the basis of their risk factors has been adopted as the main strategy in the United States.

Although the diagnosis of TB disease is confirmed by the detection of *M tuberculosis* in a clinical sample, there is no diagnostic gold standard for the diagnosis of LTBI.³ Two available but imperfect methods for identification of LTBI are the tuberculin skin test (TST) and interferon- γ release assays (IGRAs). Both methods depend on cell-mediated immunity and provide immunologic evidence of host sensitization to antigens of *M tuberculosis*. Neither method can distinguish between LTBI and TB disease, and both methods display suboptimal performance in immunocompromised patients, who are at greatest risk for progression of TB infection to TB disease. The objective of this technical report is to review the current evidence for the best uses of IGRAs in children.

TUBERCULIN SKIN TESTS

The TST was first developed by Charles Mantoux in 1907 and has been an important factor in the decline of TB disease in much of the Western world. It has existed in several forms, currently the Mantoux test, which is the intradermal injection of 5 TU of purified protein derivative (PPD) or 2 TU of PPD-RT23. PPD tuberculin solution contains dozens of TB antigens, with the exact composition varying among batches and preparations. Many of these antigens are also present in environmental nontuberculous mycobacteria (NTM) prevalent throughout the United States. A patient who mounts a cell-mediated response to tuberculin antigens has a delayed-type hypersensitivity response usually within 48 to 72 hours, causing measureable induration at the injection site.

TST results can be difficult to interpret. The test depends on accurate

intradermal injection and should be performed by an experienced individual. Interpretation requires that the family return in 48 to 72 hours. Correct interpretation of the reaction involves careful measurement of the induration determined by a provider with clinical experience in this measurement. The measurement should be recorded to the nearest millimeter of the transverse diameter of the induration. The variation in the reaction size of an individual host, determined by placement of the test simultaneously on both arms, averages 15%; the variability in measuring induration among experienced observers also varies by approximately 15% and is much greater among inexperienced personnel and untrained people, such as family members.^{4,5} Therefore, family members should not be allowed to interpret a TST result. False-negative TST results can be caused by improper handling of the PPD solution, improper placement of the test, incorrect interpretation of the results, or advanced TB disease.

Induration at the site of the TST is caused by migration of mostly mononuclear cells to the area and the inflammatory process secondary to the response of these cells. This response can be attributable to infection with *M tuberculosis*, exposure to NTM, or receipt of bacille Calmette-Guérin (BCG) vaccine.⁶ The TST cannot distinguish between TB infection and TB disease. The patient's history and the size of the induration help to determine, to some degree, which of the 3 potential causes is correct. Subjects with exposure to environmental NTM typically have indurations <10 mm, but larger reactions are not uncommon. Among populations with a low prevalence of TB but a high prevalence of exposure to environmental NTM, such as in the United States, the distribution of reactions among subjects with LTBI and those with NTM exposure will overlap

to some degree. The most effective way to minimize false-positive results is to avoid testing subjects who lack a risk factor for LTBI. When testing is performed, the recommendation has been to vary the cutoff for the size of the TST reaction considered positive. The cutoff is set at 15 mm to optimize specificity for subjects lacking LTBI risk factors, 10 mm for subjects with a risk factor for LTBI, and 5 mm to optimize sensitivity for subjects at high risk of having or developing TB disease if they have LTBI (clinical evidence of disease, recent exposure, or significant immune compromise).⁷

BCG vaccines are administered in countries with high TB burden because these vaccines reduce the risk of TB disease, particularly disseminated (miliary) and central nervous system TB. For a foreign-born child, history of BCG vaccination should be determined by examination of the vaccination record and looking for a typical BCG scar, which is usually found on the deltoid region of either arm. Some of the antigens in PPD are also found in *M bovis*-BCG, the organism in the BCG vaccines. Some subjects who are not infected with *M tuberculosis* express induration in response to the TST that reflects previous receipt of a BCG vaccination. The size of the TST reaction varies with the strain and dose of vaccine,⁸ the route of administration,⁹ age at vaccination,¹⁰ the time interval since vaccination,¹¹ and the number of BCG doses. Approximately one-half of infants who received a BCG vaccination will respond with significant induration to a TST. Although most (perhaps as many as 90%) children 5 years or older who received a BCG vaccine as an infant will not have a positive response to a TST (unless also infected with *M tuberculosis*, which may not be prevented by BCG), some will retain this response, causing a false-positive result. The induration often measures

<10 mm but can be >15 mm. Children born in most foreign countries are candidates for selective testing for LTBI, but a large number of false-positive results can occur when the TST is used on children who have received a BCG vaccine. Children who have received a BCG vaccination may also be subject to boosting by the TST (ie, the immunologic recall of hypersensitivity to antigens in the PPD that are also present on *M bovis*-BCG), which creates a false-positive TST result on repeat testing.^{12,13}

False-negative TST results can occur because of the limited ability of certain children with LTBI or TB disease to mount an appropriate delayed-type sensitivity response, especially those who are immunosuppressed either by disease (eg, advanced HIV infection, advanced TB, cancer, malnutrition) or those who have received immunosuppressive treatments (eg, corticosteroids, cancer chemotherapy, immunomodulating biologic agents [especially the tumor necrosis factor α inhibitors], or live viral vaccines [particularly measles vaccine]). Unfortunately, children for whom the TST has diminished sensitivity are those subjects most likely to progress to TB disease if infected.³

In summary, there are limitations to both the sensitivity and the specificity of the TST.¹⁴ The positive predictive value of the TST is much greater when it is applied to subjects who have a recognized risk factor for LTBI. When the TST is used in subjects lacking risk factors, the vast majority of the positive results are falsely positive, and this problem is accentuated in children who received a BCG vaccine.

INTERFERON- γ RELEASE ASSAYS

IGRAs are ex vivo blood tests that detect interferon- γ (INF- γ) release from a patient's CD4+ T lymphocytes after stimulation by antigens found on the *M tuberculosis* complex (which includes

M bovis, *Mycobacterium africanum*, *Mycobacterium microti*, and *Mycobacterium canettii*). Two IGRAs are available commercially: the QuantiFERON-TB Gold In-Tube assay (QFT; Cellestis/Qiagen, Carnegie, Australia) and the T-SPOT.TB assay (T-SPOT; Oxford Immunotec, Abingdon, United Kingdom). Both tests use early secreted antigenic target 6 and culture filter protein 10 encoded by genes located within the region of difference 1 locus of the *M tuberculosis* genome.¹⁵ The QFT uses a third antigen (TB7.7). The region of difference 1 antigens used in the 2 IGRAs are not encoded in the genomes of *M bovis*-BCG strains (although they are present on wild-type *M bovis*) or most species of NTM, specifically not on the *Mycobacterium avium* complex organisms that are the most ubiquitous pathogenic environmental NTMs. (The antigens are found on several NTM strains, including *Mycobacterium marinum*, *Mycobacterium kansasii*, *Mycobacterium szulgai*, and *Mycobacterium flavescens*.) As a result, one would expect that these tests would be more specific than the TST, yielding fewer false-positive results. Unfortunately, as with the TST, the IGRAs do not distinguish between TB infection and TB disease.

Test Characteristics

Both IGRAs are performed with positive and negative controls. The QFT assay is an enzyme-linked immunosorbent assay (ELISA) whole blood test. The result is reported as quantification of INF- γ in international units per milliliter. The test result is considered positive when the INF- γ response to the TB antigen is above the test cutoff of 0.35 IU (after subtracting the negative control value from the test antigen value). If the test result is negative, but the positive control also shows a poor response or the background response in the negative control is too high, the result is considered indeterminate (ie, neither

negative nor positive). The T-SPOT assay is an enzyme-linked immunosorbent spot (ELISPOT) assay performed on peripheral blood mononuclear cells that have been incubated with the 2 antigens. The result is reported as the number of INF- γ -producing T cells (spot-forming cells). The test result is considered positive when the number of spots in the test sample, after subtracting the number of spots in the negative control, exceeds a specific threshold (usually 8 spots). Results with a corrected spot count of 5, 6, or 7 are considered borderline (equivocal), and retesting on a different specimen is recommended by the manufacturer. If the test result is negative but the positive control also shows a poor response or if the background response in the negative control is too high, the result is termed invalid (sometimes also called indeterminate [neither negative nor positive]).

Although there are standard manufacturer instructions for performing the IGRAs, concerns have been raised about the reproducibility of the results on serial performance.^{16,17} Serial testing of health care workers at low risk of infection has often revealed unexplained conversion of IGRA results to positive and reversion to negative. Nkurunungi et al¹⁸ performed T-SPOT tests on 405 Ugandan children at age 5 years and then repeated the test 3 weeks later. Of 79 children who had an initial positive T-SPOT result, only 30 (38%) had a positive result 3 weeks later, whereas 96% of the children with an initial negative result had a negative result on repeat testing. The test agreement was better among children who were household contacts of a TB case ($\kappa = 0.77$) than among noncontacts ($\kappa = 0.29$). T-lymphocyte assays are susceptible to variability by numerous factors, including³: manufacturing issues; sample collection issues, such as inconsistencies in specimen collection, inadequate

blood volume, delays in isolation and incubation of cells, and inadequate shaking (mixing) of the QFT collection tubes; laboratory issues caused by systematic or random error; and immunologic sources, including possible boosting of the response by a recently performed TST.¹⁶ Published studies have shown a variety of differences in outcomes between the 2 basic IGRA techniques, ELISA (QFT) and ELISPOT (T-SPOT). However, in most studies, these differences have been small, and the preponderance of evidence supports the conclusion that, in terms of accuracy, neither IGRA test is preferred over the other.

Summary of Studies in Adults

As with most new diagnostic tests, the early studies were conducted on adults. Because there is no reference standard test for LTBI, specificity was estimated among low-risk subjects with no known TB exposure in a low-prevalence setting. Several meta-analyses of studies in adults have demonstrated an IGRA specificity of 95% to 100%, and, as expected, the specificity is not affected by previous BCG vaccination.^{19–21} Although TST specificity is comparable to IGRAs in adults who have not received a BCG vaccine, it is substantially lower (approximately 60%) and variable among BCG-vaccinated populations.³ In contact investigations of adults with pulmonary TB, measures of exposure have often correlated better with IGRA-positive results than with the TST because of more positive TST results in subjects with low intensity of exposure, especially within BCG-vaccinated populations.^{22,23} Test sensitivity is estimated initially among culture-confirmed cases of disease (absolute proof of infection). The sensitivity of the IGRAs in adults with culture-proven TB disease is 80% to 90% (compared with 80% for the TST). As with the TST, the IGRA sensitivity is lower in adults who are immunocompromised, especially those with

poorly suppressed concomitant HIV infection.

General Aspects of Studies in Children

Determining the sensitivity and specificity of the IGRAs for children is more difficult, and fewer studies have been published.²⁴ Most children with clinical TB disease do not have microbiologic confirmation, which means they lack the absolute proof of infection that is needed to accurately assess test sensitivity; many studies have used less reliable methods of clinical diagnosis of TB disease instead. The major difficulty for interpreting studies of LTBI is determining for discordant test results whether the negative test result is more specific or the positive test result is more sensitive. Gradients of exposure to a culture-positive case are frequently used to determine the meaning of discordant results. Four systematic reviews and meta-analyses of the available studies of the use of IGRAs in children were published in 2011 and 2012; as expected, these reviews examined many of the same studies.^{25–28} Analysis of the studies was hampered by the heterogeneous methods used, including varying definitions of a clinical case of TB disease. Studies have been performed in countries with both low and high TB burden, which often differ greatly in the severity of TB disease, rates of malnutrition in children, availability of TB diagnostic tools, structures of households where transmission often occurs, and the use of various BCG strains and vaccination techniques. Some of the published studies used ELISA and ELISPOT techniques that were different from those that are currently available commercially.

Test Specificity in Children

Although there are variable results among individual published studies,

the strongest and most consistent finding is that the IGRAs have a higher specificity for LTBI, especially in settings of low TB burden and for BCG-vaccinated children. This conclusion is based largely on comparison of test results across exposure gradients of contact investigations in schools and the community in otherwise low-burden settings.^{22,29,30} In their meta-analysis, Sun et al²⁷ included 7 studies that assessed IGRA specificity in populations with rates of BCG vaccination ranging from 0% to 100%. The pooled specificity was 100% for ELISA studies, 90% for ELISPOT studies, and 56% for TST. The specificity of ELISPOT was 89% for BCG-vaccinated children and 95% for BCG-unvaccinated children, compared with a TST specificity of 49% for BCG-vaccinated children and 93% for BCG-unvaccinated children. Five of the 7 studies concluded that agreement (measured by using κ scores) between the TST and IGRA results in BCG-unvaccinated children was higher than in vaccinated children, probably because of false-positive TST results caused by previous BCG vaccination. Lighter et al³⁰ found that among 207 children in New York, only 23% with a positive TST result had a positive QFT result and, unlike the TST results, positive QFT results correlated with increased risk of TB exposure. Chun et al³¹ also found that, among 227 BCG-vaccinated children in South Korea, the QFT results were more closely associated with exposure to a TB case than were TST results.

The most convincing evidence of increased specificity of the IGRAs would be a natural history experiment following up untreated children who have positive TST results and negative IGRA results, but these observations are scarce. Ling et al³² evaluated how clinicians in Montreal are using IGRA results to determine management of children. Among 55 children with positive TST results and negative QFT

results who were TB contacts, the negative QFT result changed management in only 3 children; 52 children received isoniazid. In 201 children with positive TST results and negative QFT results who were tested in school and immigration screenings, 145 did not receive treatment, and none developed TB disease in 1 year of follow-up. However, given the ages of the children in this study, few cases of TB disease would have been expected even if all these children were infected with *M tuberculosis*. Even given the limitations of available data, the sum of all published studies supports the concept that the IGRAs are more specific than the TST in children. Despite the greater apparent specificity of IGRAs, the decision of whether to treat a patient who has positive TST results and negative QFT results should be based on clinical judgment that takes into consideration the age of the patient, risk stratification, and the degree of exposure.

Test Sensitivity in Children

The analysis of studies in children regarding the sensitivity of the IGRAs compared with TST is far more difficult, and the results have been highly variable. The best information comes from the meta-analyses of studies of children with TB disease, diagnosed either by using culture results or clinical diagnosis.^{25–28} Sun et al²⁷ found a sensitivity for all TB disease in children of 70% for ELISA (range: 57%–96%), 62% for ELISPOT (range: 40%–100%), and 71% for the TST (range: 43%–100%). When the analysis was divided into cases of culture-confirmed TB and clinically diagnosed TB, the sensitivities were 85% and 64% for ELISA (mostly QFT), 76% and 58% for ELISPOT (mostly T-SPOT), and 85% and 66% for the TST, respectively. All 3 tests had lower sensitivity in clinically diagnosed cases; there are many possible explanations, including misdiagnosis of TB in the

clinically diagnosed group. Although this meta-analysis found no significant difference in test performance between settings of high and low TB burden, 2 other meta-analyses found the sensitivity of IGRAs to be lower in settings with high TB burden, although the number of studies was small.^{25,26} Two more recent studies conducted in settings with high TB burden also found low sensitivity of IGRAs for TB disease, and they did not add value to the clinical data and conventional tests for diagnosis of TB disease in these children.^{33,34}

The sum of all published studies suggests that the IGRAs are not more sensitive than TST (likely less sensitive in settings of high TB burden) or other measures of determining TB disease in children and cannot be used to rule out TB disease. However, there is some evidence that the sensitivity is increased when both a TST and IGRA are performed, and the use of both tests will increase the rate of positive results in high-risk settings. Hill et al³⁵ investigated child household contacts of adult TB cases in The Gambia. Overall agreement between the TST and ELISPOT was 83%, with each test being positive in 32% of the children, and neither test was affected by BCG vaccination. An additional Gambian study demonstrated a 10% sensitivity benefit for using both a TST and IGRA in children at high risk.³⁶

Indeterminate/Invalid Results in Children

Indeterminate (preferably called invalid in relation to the T-SPOT test) results occur most commonly when the test sample is negative but the positive control has insufficient activity; however, they also occur when the background activity in the negative control is too high. Indeterminate/invalid results may occur because of technical factors, most frequently inadequate shaking of the QFT tubes after the patient's sample has been added. Rates of indeterminate/

invalid results among children have varied between 0% and 35%, but most studies have reported rates in the range of 0% to 10%.^{26,37–42} The rates have been slightly lower with the more recent versions of the commercially available tests. Indeterminate/invalid rates generally are higher among subjects with compromised immune systems whose T lymphocytes cannot mount an adequate response to the positive control, especially people with HIV infection⁴³; they have also been noted to be higher in children with poorly controlled inflammatory bowel disease, hepatitis, malaria, and helminthic infection.^{44,45} Many, but not all, studies have found that otherwise healthy children younger than 5 years are more likely to have indeterminate/invalid test results than older children and adolescents.^{40,46–49}

Test Performance in Immunocompromised Children

Data are scarce for determining the sensitivity and specificity of the IGRAs for immunocompromised children who are at increased risk of developing TB disease if they are infected with *M tuberculosis*. Three systematic reviews of the performance of IGRAs in HIV-infected subjects, mostly adults, concluded that the T-SPOT test may be slightly more sensitive than the QFT (72% vs 61%), but neither was more sensitive than the TST.^{43,50,51} Several small studies have included children with HIV infection and produced varied results; in general, the IGRAs perform poorly and have less concordance with the TST in children with advanced HIV infection, especially if they have concomitant malnutrition.^{52,53} Two small studies have examined the performance of the IGRAs and the TST in children with cancer. Stefan et al⁵⁴ found that among 37 children with untreated cancer in Cape Town, South Africa (a region with extremely high

rates of TB), 7 had positive results with at least 1 test; there was a higher rate of positive results with the T-SPOT, poor concordance among the TST and IGRAs, and a high rate of test failure because of low cell counts. During a contact investigation of 18 children in a pediatric hematology-oncology ward after a patient was found to have pulmonary TB, only 2 patients had a positive T-SPOT result, and this test had more invalid/indeterminate results than the QFT.⁵⁵

Screening for TB risk factors should be performed before any immunosuppressing therapy is given, but it is especially important before therapy with immunomodulating biologic agents, such as monoclonal antibodies against tumor necrosis factor α .³ This topic has been the subject of many small studies in adults that were reviewed in 2 papers.^{56,57} Unfortunately, there are no published studies involving children. For these patients, test sensitivity is more important than specificity because of the increased risk of progression of LTBI to TB disease. In most of the published studies, adult patients had already been treated with a variety of immunosuppressing agents, which may have affected the results of the TST or IGRAs. Rates of indeterminate/invalid results were higher than usual in these patients because of immunosuppression by both disease and drugs. The current evidence does not consistently suggest that IGRAs are better than the TST in identifying subjects who will benefit from treatment of LTBI. It is commonly recommended that all patients, regardless of specific TB risk factors, who will be receiving an immunomodulating biologic agent should be tested for LTBI before starting the therapy. Many experts have suggested that both the TST and an IGRA should be performed for patients who also have a risk factor for LTBI, and appropriate treatment of LTBI should be started if either test result

is positive once TB disease has been ruled out.^{56–60}

Effect of Age on Test Results

There has been a hesitancy to use IGRAs in children younger than 5 years because of a lack of data for this age group and concerns about inadequate sensitivity of the IGRAs. Because infants and young children are more likely than older children to have progression from untreated LTBI to TB disease and young children are more prone to develop serious forms of TB, failure to accurately diagnose TB infection in this age group can have dire consequences.⁷ Resolution of this issue has been hampered by the lack of a reference standard for LTBI. The earliest studies suggested that IGRA sensitivity is diminished in young children, but the results were inconsistent.^{26,41} However, several more recent studies have demonstrated better performance of the commercially available IGRAs in young children. Debord et al⁶¹ found that among 19 children with TB disease, 6 of 10 children younger than 2 years and 9 of 9 children 2 to 5 years of age had a positive QFT result. Moyo et al⁶² studied 397 children in South Africa who were younger than 3 years and were suspected of having TB disease. Agreement between the QFT and TST was 94%, but both tests had lower sensitivity for TB disease (38% for QFT and 35% for the TST) than has been reported in older age groups. Although the IGRAs have low sensitivity for detecting TB disease in young children whose immune responses may be blunted by malnutrition and TB itself, it is not clear whether they have a higher sensitivity for detecting TB infection in otherwise healthy children. Pavić et al⁶³ studied 142 healthy BCG-vaccinated children in Croatia who had recently been exposed to infectious TB disease. Both

the QFT and the TST had rates of positive results that were associated with degree of exposure, and there was no evidence that age affected QFT performance. Critselis et al⁴⁹ performed a TST and QFT in 761 healthy Greek children in 4 age groups who were referred for several indications. Among the 198 children younger than 5 years (74 were younger than 2 years), infants with positive QFT results produced a greater mean titer of INF- γ than older children and adolescents. Agreement between the TST and QFT results was not significantly different between younger and older children. However, the rate of indeterminate results was significantly greater in younger (8.1%) than in older (2.7%) children. It is clear that the use of the TST in infants and young children who received a BCG vaccine will lead to some false-positive results caused by cross-reaction with the BCG. Although some experts support the use of IGRAs to test for LTBI in infants and young children, especially those at low risk of TB infection who have received a BCG vaccine, others do not recommend their routine use in children younger than 5 years until more supportive data are available.

In summary, if an IGRA is performed in an infant or young child, a positive result likely indicates infection with *M tuberculosis*, but a negative result does not rule it out. The rates of indeterminate/invalid results seem to be higher in infants and toddlers than in older children.

Strategies for the Use of IGRAs in Children

Some of the major differences between the TST and the IGRAs are summarized in Table 1. The basis for deciding which diagnostic test to use is fundamentally different for a child than for an adult, and it differs between the diagnosis of LTBI and TB disease. When testing otherwise healthy subjects, the purpose of the TST or an IGRA is to determine

whether the person is infected with *M tuberculosis* and will benefit from treatment. In truth, the positive predictive value of both tests for the development of TB disease is poor in adults and children 5 years or older because, at most, 5% to 10% of those who test positive and go untreated will develop TB disease in their lifetime. In this regard, there is little difference between the TST and the IGRAs. However, children younger than 2 years with untreated TB infection have a 30% to 40% risk of developing TB disease within 1 year; therefore, optimizing test sensitivity is important for this age group. In addition, because children tend to tolerate the treatment of LTBI much better than adults, their risk of adverse events caused by treatment is less. However, test specificity is also an issue, especially for children who have received a BCG vaccine or who have a likelihood of exposure to NTM in their environment; testing them by using the TST will lead to an appreciable proportion of false-positive results when the prevalence of TB infection is low, as in the United States.

Both the TST and the IGRAs are imperfect methods. As a result, **only children who have a risk factor for**

TB infection, have a disease or condition that may require significant therapeutic immunosuppression, or are suspected of having TB disease should be tested with either method. However, a negative result from either type of test is not reliable for excluding the presence of TB disease. Deciding which test to use involves a consideration of sensitivity and specificity. When high specificity is desired (eg, otherwise low-risk BCG-vaccinated children), the IGRAs are the superior tests. Neither method has a clear advantage in sensitivity; when sensitivity is the main concern, a positive result with either the TST or IGRA should be considered indicative of infection with *M tuberculosis*. When sensitivity is paramount, such as high suspicion of TB disease or testing a child who has a TB risk factor and who will soon receive an immunomodulating biologic agent, both an IGRA and a TST should be performed. Performing both tests will lower the overall specificity and lead to some false-positive results, but in children with a high risk of progression to TB disease, this outcome is often an acceptable trade-off.

TABLE 1 Comparison of the TST and IGRAs

Characteristic	TST	IGRA
Antigens used	Many; PPD	3 (QFT) or 2 (T-SPOT)
Sample	Intradermal injection	Blood draw
Patient visits required	2	1
Distinguish between LTBI and TB disease	No	No
Cross-reactivity with BCG	Yes	No
Cross-reactivity with NTM	Yes	Only rare species ^a
Differing positive values by risk	Yes (5-10-15)	No
Causes boosting	Yes	No
Subject to boosting by previous TST	Yes	Possible
Durability over time (stays positive with or without treatment)	Yes	Unknown
Difficulties with test reproducibility	Yes	Yes
Relative cost	Lower	Higher
Location of need for trained staff	"Bedside"	Laboratory
Estimated specificity in BCG-unvaccinated children	95% to 100%	90% to 95%
Estimated specificity in BCG-vaccinated children	49% to 65%	89% to 100%
Estimated sensitivity (confirmed TB disease)	75% to 85%	80% to 85%
Estimated sensitivity (clinical TB disease)	50% to 70%	60% to 80%

^a *M marinum*, *M kansasii*, *M szulgai*, and *M flavescens*.

Figure 1 and Table 2 show potential strategies for testing. Some specific points are:

- Only children who have a risk factor for TB infection, are about to undergo significant immunosuppression, or are suspected of having TB disease should be tested with a TST or an IGRA.
- There is no compelling evidence to support the use of one IGRA over the other.
- If the child has been exposed recently to an infectious case of TB disease, he or she should be evaluated and treated accordingly if either a TST or IGRA result is interpreted to be positive.
- Even with a negative initial test result, contacts of a person with known TB

should be retested in 8 to 10 weeks regardless of whether the initial test used was a TST or IGRA.

- For children 5 years or older, either the TST or an IGRA can be used.
- For children 5 years or older who have received a BCG vaccine, 2 strategies can be used:
 - (1) an IGRA can be used and the result acted on; or
 - (2) a TST can be performed, and if the result is negative, no further testing is necessary; if the result is positive, an IGRA can be performed, and its result acted on.
- When testing for LTBI, some experts will use an IGRA in children 2 to 4 years of age, especially if they have received a BCG vaccine. Most experts

do not currently use an IGRA when testing for LTBI for children younger than 2 years because of lack of data for this age group and the high risk of progression to disease.

- When evaluating a child of any age for TB disease, both a TST and one or both IGRAs can be performed to maximize sensitivity. However, neither method can be used to rule out TB disease.
- For children diagnosed with an immunosuppressing disease or who are about to start immunosuppressive therapy of any kind, testing should be performed with either a TST or IGRA, even in the absence of a recognized TB risk factor. If the child does have a TB risk factor,

FIGURE 1

An algorithm for the use of the TST and IGRAs in children. Entry into the algorithm assumes that the child has at least 1 risk factor for TB infection.

TABLE 2 Suggested Uses of TST and IGRA in Children

TST preferred

- Children younger than 5 y^a

IGRA preferred, TST acceptable

- Children 5 y or older who have received BCG vaccine
- Children 5 y or older who are unlikely to return for the TST reading

Both the TST and an IGRA should be considered when:

- The initial and repeat IGRA results are indeterminate/invalid
- The initial test (TST or IGRA) result is *negative* and:
 - There is clinical suspicion of TB disease^b
 - The child has a TB risk factor and is at high risk of progression and poor outcome (especially therapy with an immunomodulating biologic agent, such as a TNF- α antagonist)^b
- The initial TST is *positive* and:
 - The patient is 5 years or older and has a history of BCG vaccination
 - Additional evidence is needed to increase adherence with therapy

TNF- α , tumor necrosis factor α

^a Some experts will use an IGRA in children 2 to 4 years of age, especially if they have received a BCG vaccine but have no other significant risk factors. Most experts do not use an IGRA for children younger than 2 years because of lack of data for this age group and the high risk of progression to disease.

^b A positive result of either test is considered significant in these groups.

testing should be performed with both the TST and an IGRA.

- When an IGRA result is indeterminate/invalid, either a repeat IGRA test using the same or the other IGRA can be performed, ensuring proper technique of specimen collection and processing, or a TST can be performed.

CONCLUSIONS

The IGRAs are an advance in the diagnosis of TB infection and disease in children. They have greater specificity than the TST and can greatly reduce the number of false-positive results and unnecessary treatment in children who have received a BCG vaccine or who have been exposed to NTM. The sensitivity of the IGRAs seems to be no better than the TST, but combining them with a TST may increase sensitivity for the diagnosis of TB disease or the detection of TB infection in children at particularly high risk of having progression from TB infection to TB disease. For children 5 years or older, IGRAs can be

used in any situation in which a TST would be used. Because of the relative lack of data concerning the reliability of negative IGRA results in young children and the need for sensitivity in these children because of their increased risk of progression to disease, the IGRAs should not be used to detect LTBI in children younger than 2 years. The IGRAs have the advantages of requiring only a single health visit and have more objective measurement in the laboratory. Although these tests are more expensive than the TST, their use may be more economical than the TST because of the elimination of many false-positive results.⁶⁴

abstract

FREE

Many women of reproductive age in the United States are marginally iodine deficient, perhaps because the salt in processed foods is not iodized. Iodine deficiency, per se, can interfere with normal brain development in their offspring; in addition, it increases vulnerability to the effects of certain environmental pollutants, such as nitrate, thiocyanate, and perchlorate. Although pregnant and lactating women should take a supplement containing adequate iodide, only about 15% do so. Such supplements, however, may not contain enough iodide and may not be labeled accurately. The American Thyroid Association recommends that pregnant and lactating women take a supplement with adequate iodide. The American Academy of Pediatrics recommends that pregnant and lactating women also avoid exposure to excess nitrate, which would usually occur from contaminated well water, and thiocyanate, which is in cigarette smoke. Perchlorate is currently a candidate for regulation as a water pollutant. The Environmental Protection Agency should proceed with appropriate regulation, and the Food and Drug Administration should address the mislabeling of the iodine content of prenatal/lactation supplements. *Pediatrics* 2014;133:1163–1166

ADEQUACY OF IODINE INTAKE IN THE UNITED STATES

Adequate iodine intake, usually as iodide, is necessary to produce thyroid hormone. Adequate thyroid hormone production is critical in pregnant women and neonates because thyroid hormone is required for brain development in children.¹ Severe, untreated hypothyroidism in infancy results in irreversible cretinism, but milder iodine deficiency can also affect cognitive development of the child. The “goiter belt” of endemic iodine deficiency in the United States had largely been eliminated by iodizing table salt in 1924; however, iodine deficiency increased from the 1970s through the 1990s, and approximately one-third of pregnant women in the United States are marginally iodine deficient.^{2,3} Processed foods in the United States are prepared with noniodized salt,⁴ and consumption of these processed foods has increased. Although studies of cognitive development in infants whose mothers were marginally iodine deficient revealed inconsistent results,^{5,6} any morbidity resulting from iodine deficiency can and should be prevented. Although there are a few instances in which governments have required the use of

iodized salt in processed foods,⁷ this option has not been well studied and is not likely to occur in the United States soon. The Salt Institute, the trade group for salt manufacturers, has a goal of universal salt iodization, but it claims that companies are reluctant to switch to iodized salt for fear that taste or other characteristics of the processed food would be altered.

The American Thyroid Association⁸ and the National Academy of Sciences⁹ recommend that lactating women have an intake of 290 μg of iodide per day, which generally requires a supplement with 150 μg of iodide. In the United States, although most pregnant and lactating women take supplements, only 15% to 20% take supplements that contain any iodide.¹⁰ Many prenatal/lactation vitamins do not contain iodide, and those containing iodide are often formulated to have 150 μg or less of potassium iodide, which should yield approximately 120 μg or less of iodide, which is below the recommended amount of 150 μg . In addition, there is wide variability in the measured iodide content of supplements.¹¹

POLLUTANT CHEMICALS AND IODINE DEFICIENCY

Commonly encountered environmental chemicals might augment the effects of iodine deficiency by competing for transport by the sodium-iodide symporter (NIS). The NIS is an integral plasma membrane glycoprotein found in the thyroid gland and the lactating mammary gland, among other tissues.¹² The NIS mediates the active transport of iodide into the thyroid follicular cells, making it available to iodinate dehydroxylated tyrosine for the first step in thyroid hormone synthesis. In the mammary gland, the NIS mediates transport of iodide into milk, making it available

to the infant. Although the NIS has a high affinity for iodide, other anions, such as thiocyanate, nitrate, and perchlorate, can compete with (and be transported as) iodide and thus decrease iodide concentration within the thyroid gland or milk. Although such transport might be expected to lead to increased concentrations of nitrate, thiocyanate, and perchlorate in human milk, only perchlorate exposure and excretion have been found to be significantly higher in breastfed infants under normal circumstances.^{13,14}

Thiocyanate and nitrate are well-known and commonly encountered chemicals. Exposure to thiocyanate comes from cruciferous vegetables and tobacco smoke (including secondhand smoke), and exposure to nitrate comes from drinking water and some leafy and root vegetables. Perchlorate (ClO_4^-) may be less familiar. It is an inorganic anion used industrially as an oxidizer for rocket fuels and propellants and in explosives. It also occurs naturally, usually in arid regions, such as in the southwestern United States. Perchlorate is 10 to 100 times more potent than iodide or the other anions in competing for the NIS. It has become a widespread environmental contaminant. The Environmental Protection Agency (EPA) detected perchlorate in approximately 4% of US public drinking water systems.¹⁵ Perchlorate has also been detected in cow milk as well as in a variety of other foods. In a nationwide survey, the US Food and Drug Administration (FDA) detected perchlorate in at least 1 sample of 74% of foods analyzed.¹⁶ Analysis of samples gathered in the NHANES (2001–2002) revealed widespread human exposure to perchlorate; all 2820 spot urine specimens analyzed contained perchlorate, and the median urine perchlorate concentration in the US population was 3.6 $\mu\text{g/g}$ of creatinine.¹⁷ Perchlorate

competitively inhibits iodide uptake, and high-dose exposure will decrease thyroid function.^{18,19} There is some evidence that perchlorate interferes with thyroid hormone economy at background exposures in the United States. In the NHANES (2001–2002), female participants 12 years and older with lower iodide status and higher urinary perchlorate had higher serum thyroid-stimulating hormone (TSH) and lower serum thyroxine concentrations.¹⁷ In a smaller study in infants, both boys and girls with lower urinary iodide and higher perchlorate concentrations had higher urinary TSH and, unexpectedly, higher thyroxine concentrations.²⁰ That study also reported increases in TSH concentration associated with thiocyanate and nitrate concentrations in urine of infants.

The EPA, in February 2011, made a regulatory determination for perchlorate in accordance with the Safe Drinking Water Act.²¹ This is the first of several steps in the direction of limiting the amount of perchlorate in drinking water, which should ultimately decrease exposure to mothers and infants. This action initiates a process to develop and establish a National Primary Drinking Water Regulation. Once the National Primary Drinking Water Regulation is finalized, certain public water supplies will be required to take action to comply with the regulation in accordance with the schedule specified in the regulation.

Iodine deficiency is undesirable *per se* because of its potential harm to the developing nervous system. Iodine deficiency may also make the mother and child more vulnerable to environmental agents that compete with iodine for transport into thyroid tissue. The effective regulation of perchlorate by the EPA should decrease exposure but it will not do so

quickly. With regard to thiocyanate and nitrate, young infants should not be exposed to tobacco smoke or drinking water with excess nitrate; few consume enough cruciferous, leafy, or root vegetables for these sources to be of concern. For breastfeeding mothers, perchlorate exposure may be currently unavoidable, but breastfeeding should not be discouraged because of the presence of perchlorate or other environmental chemicals. Nitrate and thiocyanate in the maternal diet do not appear to increase a breastfed child's exposure. In summary, many US women of reproductive age are marginally iodine deficient. Iodine deficiency per se can interfere with normal brain development in their offspring; in addition, it increases vulnerability to the effects of certain environmental pollutants. Women should take a prenatal/lactation supplement with adequate iodide. Such supplements are not currently labeled accurately, but the FDA is moving to correct this situation.

RECOMMENDATIONS FOR CLINICIANS

Pediatricians should be aware that pregnant women and breastfeeding mothers, and thus their infants, may be iodine deficient. Breastfeeding mothers should take a supplement that includes at least 150 μg of iodide and use iodized table salt (combined iodide intake should be between 290 and 1100 μg of iodide per day). If the mother is vegan or does not consume dairy or fish, testing urine to check for iodine deficiency may be indicated. If an opportunity arises to advise a woman who is pregnant or planning to become pregnant about supplementation, the pediatrician should provide similar guidance.

Breastfeeding mothers should avoid excess nitrate both to avoid potential

interference with iodide transport and to prevent methemoglobinemia in their infants.²² Water is the usual source of excess nitrate. Municipal water supplies are regulated, but nitrate is a common pollutant of private wells. The American Academy of Pediatrics (AAP) recommends that well water be checked annually.²³

Interested pediatricians should contact the AAP Department of Federal Affairs about ways they can support regulation by the FDA and EPA. Both agencies need to recognize the hazard to children posed by the current situation.

Tobacco smoke is a source of thiocyanate exposure. The AAP has a detailed policy about the prevention of tobacco smoke exposure.²⁴ Pregnant women should be advised not to smoke and to avoid all exposures to secondhand tobacco smoke.

RECOMMENDATIONS FOR GOVERNMENT

The current reported state of discordance between the label and the actual content of iodide in supplements is unacceptable. As Leung et al¹¹ stated, "Manufacturers of prenatal multivitamins in the United States should be encouraged to use only potassium iodide, to maintain consistency in labeling, and to ensure that these vitamins contain 150 μg of supplemental daily iodide by including at least 197 μg of potassium iodide per daily dose, as recommended by the American Thyroid Association." The FDA is aware of this situation and was investigating it as of fall 2013. The FDA should attempt to correct this situation and, if voluntary action on the part of the suppliers is insufficient, do what is necessary to allow consumers to identify and use iodide supplements with confidence.

The EPA has begun the regulatory process to establish a national primary drinking water regulation for perchlorate. Because of the potential effect on children, the AAP encourages the EPA to complete the regulatory process in as expeditious a manner as possible.

State and local governments should enact clean-air and smoke-free environment ordinances and legislation in their communities and states, particularly for environments in which children learn, live, and play, such as schools, multiunit housing, public parks, child care settings, public beaches, sidewalks, restaurants, and sporting arenas. These environments should be smoke free, even when children are not present.²⁴

POLICY STATEMENT

Literacy Promotion: An Essential Component of Primary Care Pediatric Practice

abstract

FREE

Reading regularly with young children stimulates optimal patterns of brain development and strengthens parent-child relationships at a critical time in child development, which, in turn, builds language, literacy, and social-emotional skills that last a lifetime. Pediatric providers have a unique opportunity to encourage parents to engage in this important and enjoyable activity with their children beginning in infancy. Research has revealed that parents listen and children learn as a result of literacy promotion by pediatricians, which provides a practical and evidence-based opportunity to support early brain development in primary care practice. The American Academy of Pediatrics (AAP) recommends that pediatric providers promote early literacy development for children beginning in infancy and continuing at least until the age of kindergarten entry by (1) advising all parents that reading aloud with young children can enhance parent-child relationships and prepare young minds to learn language and early literacy skills; (2) counseling all parents about developmentally appropriate shared-reading activities that are enjoyable for children and their parents and offer language-rich exposure to books, pictures, and the written word; (3) providing developmentally appropriate books given at health supervision visits for all high-risk, low-income young children; (4) using a robust spectrum of options to support and promote these efforts; and (5) partnering with other child advocates to influence national messaging and policies that support and promote these key early shared-reading experiences. The AAP supports federal and state funding for children's books to be provided at pediatric health supervision visits to children at high risk living at or near the poverty threshold and the integration of literacy promotion, an essential component of pediatric primary care, into pediatric resident education. This policy statement is supported by the AAP technical report "School Readiness" and supports the AAP policy statement "Early Childhood Adversity, Toxic Stress, and the Role of the Pediatrician: Translating Developmental Science Into Lifelong Health." *Pediatrics* 2014;134:404–409

STATEMENT OF NEED

Reading aloud with young children is one of the most effective ways to expose them to enriched language and to encourage specific early literacy skills needed to promote school readiness. Indeed, early, regular parent-child reading may be an epigenetic factor associated with later reading success.^{1,2} Yet, every year, more than 1 in 3 American children

start kindergarten without the language skills they need to learn to read. Reading proficiency by the third grade is the most important predictor of high school graduation and career success. Approximately two-thirds of children each year in the United States and 80% of those living below the poverty threshold fail to develop reading proficiency by the end of the third grade. Children from low-income families hear fewer words in early childhood and know fewer words by 3 years of age than do children from more advantaged families. Children from low-income families have fewer literacy resources within the home, are less likely to be read to regularly, and are more likely to experience early childhood adversity and toxic stress at an early age, all resulting in a significant learning disadvantage, even before they have access to early preschool interventions.^{3–6}

The 2011–2012 National Survey of Children's Health found that 60% of American children from birth to 5 years of age from families whose incomes were 400% of the federal poverty threshold or greater were read to daily, and only 34% of children from families whose incomes were below 100% of the poverty threshold were read to daily.⁷ These numbers indicate that, even in higher-income families, many children do not experience the enhanced engagement and language-rich parent-child interactions, including book handling, print exposure, and other early literacy experiences, afforded by daily shared reading. All families face issues of limited time, limited parental understanding of the key role of reading aloud, and competition for the child's interest and attention from other sources of entertainment, such as electronic media.⁸ In contrast to often either passive or solitary electronic media exposure, parents reading with young children is a very personal and nurturing experience that promotes parent-child interaction,

social-emotional development, and language and literacy skills during this critical period of early brain and child development.

LANGUAGE AND LITERACY DISPARITIES

Reading with children in their infancy and preschool years is associated with higher language skills at school entry and with childhood literacy acquisition.^{9–11} After controlling for family education and socioeconomic status, the literacy-related qualities of a child's home are associated with language skill development.^{12,13} Earlier age of initiation of reading aloud with a child has been shown to be associated with better preschool language skills and increased interest in reading.¹⁴ Reading aloud with young children has been found to increase the richness of the vocabulary to which they are exposed as well as the complexity of syntax.¹⁵ In addition, books and early conversations and play around books and reading stimulate increased interaction between the adult and child.¹⁶ These interactions build nurturing relationships that are critical for the child's cognitive, language, and social-emotional development.¹⁷

Hart and Risley⁵ identified dramatic differences in early language exposure of 1- and 2-year-olds in low-income families compared with children in higher-income families. Cognitive and linguistic differences in children from talkative versus taciturn families were impressive by 3 years of age and persisted into school age. Indeed, 60% of the variance in vocabulary in these children at 8 and 9 years of age could be explained by their exposure to language at home, before they were 3 years old. Book sharing has been shown to promote social interaction between caregiver and child and to encourage literacy development.^{16,17} Children's literacy skills at school entry and in kindergarten and first grade often predict their later reading success.^{18–20}

Children from low socioeconomic backgrounds are significantly more likely to have reading problems, to repeat a grade, and to have learning disabilities diagnosed.^{21,22} Poor reading skills in adults are associated with poor economic potential and with the perpetuation of cycles of poverty, poor health, and dependency across the life course.²³

DATA LINKING HEALTH TO LITERACY

Health literacy is “the degree to which individuals can obtain, process, and understand basic health information and services needed to make appropriate health decisions.”²⁴ The 2003 National Adult Assessment of Literacy estimated that 14% of US adults had below basic literacy and 22% more had only basic literacy, which results in more than 90 million adults in the United States who may lack the literacy needed to effectively negotiate the health care system.²⁵ Research has revealed compelling associations of diminished disease knowledge, decreased utilization of preventive services, increased hospitalization, poorer overall health status, poorer control of chronic illness, and higher mortality in adults with limited health literacy.^{26–30} This interplay of health and development means that low literacy and related low health literacy in parents of young children pose a range of additional risks, with studies showing increased developmental risk for children associated with reduced reading aloud and increased health risk related to medication dosing errors and lower rates of adherence to medical regimens.^{31,32}

DATA SUPPORTING OFFICE-BASED PRACTICE OF LITERACY PROMOTION AS AN EFFECTIVE INTERVENTION

There are many literacy programs that promote reading to children. Reach Out and Read (ROR) is the most widely studied and disseminated model of

literacy promotion in the child's medical home. Multiple studies in high-risk populations show that the ROR model, which includes advising parents of infants, toddlers, and preschool-aged children about the importance of reading aloud, counseling parents about specific book-related strategies, modeling, and providing developmentally appropriate books to children at health supervision visits, results in parents being more likely to read with their children regularly.^{1,35–35} In addition, these children are more likely to have significantly improved language development by the age of 24 months compared with their peers who did not participate in these programs.¹ Parents participating in ROR reported a more positive attitude toward books and reading. For example, when asked to name favorite activities with their child or their child's favorite activities, parents were significantly more likely to mention looking at books and reading aloud than were parents in control groups who had not received the ROR intervention. This significant increase in parents viewing reading with young children as a favorite activity has been found in English- and Spanish-speaking parents, including recent immigrant populations.^{1,35,36} One study evaluated families who spoke languages in which no books were available. These families were given English books and still showed increased positive attitudes and practices.³⁷

Well-designed studies using appropriately matched comparison families or randomized controlled trials of ROR have revealed differences in children's expressive and receptive language.^{1,2,36,38} In one study, there was a 6-month developmental increase in receptive language skills of children (average age, 4 years) whose families were participating in ROR, and children with more contacts with ROR had larger increases in their language skills.² In another

study, larger vocabulary size was evident in intervention children by the time they were 18 to 25 months old.¹ ROR has also been found to contribute positively to a child's home literacy environment.³⁹ A multicenter study of 19 primary care sites in 10 states before and after introducing ROR showed increased parental support for reading aloud after the program was implemented.⁴⁰ In addition, a program modeled after ROR for implementation in collaboration with the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) was shown to be associated with improved school readiness.⁴¹ A recent randomized controlled trial of enhanced intervention building on ROR showed that additional intervention during the first 6 months of life leads to increased reading activities in infancy, reduced infant electronic media exposure, and increased parent-child interactions in children from low-income, immigrant, inner-city families. This reduced media exposure was a direct result of the increase in reading activities.^{42,43}

Research, in summary, shows that in populations at risk, participation in the ROR intervention is associated with markedly more positive attitudes toward reading aloud, more frequent reading aloud by parents, improved parent-child interactions, improvements in the home literacy environment, and significant increases in expressive and receptive language in early childhood.⁴⁴

PROGRESS INTEGRATING LITERACY PROMOTION INTO PRIMARY CARE AND THE NEED FOR ADVOCACY

The ROR model has been voluntarily adopted by more than 5000 pediatric primary care sites serving children at risk and has thus been field tested widely and found to integrate effectively into primary care in a variety of settings. The model includes training in the techniques for using books to enrich

and expedite primary care visits. This training is already incorporated into the majority of pediatric residency programs, so newly trained pediatricians are likely to have learned pediatric literacy promotion as part of how to deliver quality primary care, again reflecting the evidence base supporting the efficacy of the intervention. Initiatives partnering with the AAP are currently underway to increase literacy promotion and the adoption of the ROR model to serve several important groups, including American Indian, Native Hawaiian, and Alaska Native populations.⁴⁵ Another initiative, partnering with the AAP Section on Uniformed Services, is developing ways to foster literacy promotion in medical facilities serving military families. Local and national partnerships with public libraries, adult and family literacy programs, child care providers, schools, and businesses can help pediatricians connect families to more books, more skills, and more opportunities to facilitate the safe, stable, and nurturing relationships associated with long-term academic success and health.

Support and advocacy from the AAP will make it more likely that financial support can be found for pediatricians who want to follow this model. Many pediatricians believe that their patients could benefit from this intervention, but ongoing book supply is often a barrier, as are the time pressures already crowding the primary care visit. Costs in both books and time can be offset in great measure by the many ways that a book can enrich the interactions among children, parents, and pediatric providers at visits. The simple practice of incorporating a book into the health supervision visit allows for direct observation of emergent language and literacy skills and parent-child interactions around shared reading, as well as an opportunity to provide concrete guidance around language, development, and daily routines. In addition, books and

the guidance that accompanies them improve families' satisfaction with the care and advice they receive and strengthen their bond with their primary care provider and medical home.⁴⁶

RECOMMENDATIONS FOR PEDIATRICIANS

The AAP recommends that pediatric providers promote early literacy development as an important evidence-based intervention at health supervision visits for children beginning in infancy and continuing at least until the age of school entry by engaging in the following:

1. Advising all parents that reading aloud with their young children can enrich parent-child interactions and relationships, which enhances their children's social-emotional development while building brain circuits to prepare children to learn language and early literacy skills.
2. Counseling all parents about developmentally appropriate reading activities that are enjoyable for the child and the parents and offer language-rich exposure to books and pictures and the written word.
3. Providing developmentally, culturally, and linguistically appropriate books at health supervision visits for all high-risk, low-income children and identifying mechanisms to obtain these books so that this does not become a financial burden for pediatric practices.
4. Using a robust spectrum of options to support and promote these efforts, including wall posters and parent information materials that are culturally competent and accessible to those with limited literacy skills themselves, as well as information about the locations of and services offered by their local public libraries and mechanisms for accessing books for distribution. The AAP provides a literacy toolkit

(available at www2.aap.org/literacy/index.cfm) for pediatric and educational professionals and for parents to support this work.

5. Partnering with other child advocates to influence national messaging and policies that support and promote these key early shared-reading experiences.

In addition, as described in the AAP technical report "School Readiness," pediatric providers can also promote the "5 Rs" of early education:

1. Reading together as a daily fun family activity;
2. Rhyming, playing, talking, singing, and cuddling together throughout the day;
3. Routines and regular times for meals, play, and sleeping, which help children know what they can expect and what is expected from them;
4. Rewards for everyday successes, particularly for effort toward worthwhile goals such as helping, realizing that praise from those closest to a child is a very potent reward; and
5. Relationships that are reciprocal, nurturing, purposeful, and enduring, which are the foundation of a healthy early brain and child development.³

RECOMMENDATIONS FOR POLICY MAKERS

1. The AAP supports incorporation of literacy promotion and training related to language and literacy development into pediatric resident education. The integration of literacy promotion as a key component of primary care should be taught in resident continuity experiences and evaluated as an element of competency-based pediatric medical education.
2. The AAP supports federal and state funding for children's books to be provided at pediatric health supervision visits for children at high risk as

well as the incorporation of funding for children's books in managed care and government insurance programs for children at high risk.

3. The AAP supports research on the effects of pediatric early literacy promotion on child health and educational outcomes and research on best practices for literacy promotion in the context of both pediatric practice and of residency education.

SUMMARY

Providing books at pediatric primary care visits to families at economic and social risk, together with developmentally appropriate anticipatory guidance encouraging parents to read aloud with their children, has a powerful effect on the home environment of young children. It directly affects language development, a major factor in school readiness, during the critical period of early brain development. The costs of these books, of training primary care providers, and of incorporating these strategies into the primary care visit constitute an investment in infants, toddlers, and preschool children directed at their language, literacy, social-emotional, and life course development. As Professor James Heckman argued in his keynote address at the 2007 AAP National Conference and Exhibition, programs that invest in children at the earliest ages have the highest rates of return. By initiating early support for reading aloud, modifying the home environment to be richer in print, and advising parents about enjoyable and playful book-related strategies that will increase their children's language and early literacy skills within the context of their critically important nurturing relationships with their parents and caregivers, pediatric providers can leverage their unique opportunity to influence children in the very early years of life and to create important long-term relationships with families.

All families need to hear the important message that reading aloud to their children is crucial, especially in an era in which competing entertainment imperatives, such as screen time (television, cinema, video games, and computers), may limit family interactions and live language exposures of even very young children.^{47,48} Although most research has focused on literacy promotion for families of lower socioeconomic status, pediatricians should remember to educate all families about the importance of reading aloud to young children because even in affluent and educated families with plenty of books at home, many parents do not read with their children on a daily basis. Promoting literacy with parents of children beginning in infancy supports the recommendations of the AAP that children younger than 2 years not view electronic media and that older children and youth have no more than 2

hours daily of media exposure by offering parents a positive alternative for entertaining young children, for nurturing early relationships, and for developing healthy bedtime routines. The positive reinforcement of repeated developmentally appropriate encouragement in the context of the primary care visit reminds parents again and again of the importance of their “face time,” interactive conversations, and their own evolving and essential relationship with their children, which is critical to setting a young child’s developmental trajectory and life course.

- *Policy Statement*

POLICY STATEMENT

Maintaining and Improving the Oral Health of Young Children

abstract

FREE

Oral health is an integral part of the overall health of children. Dental caries is a common and chronic disease process with significant short- and long-term consequences. The prevalence of dental caries for the youngest of children has not decreased over the past decade, despite improvements for older children. As health care professionals responsible for the overall health of children, pediatricians frequently confront morbidity associated with dental caries. Because the youngest children visit the pediatrician more often than they visit the dentist, it is important that pediatricians be knowledgeable about the disease process of dental caries, prevention of the disease, and interventions available to the pediatrician and the family to maintain and restore health. *Pediatrics* 2014;134:1224–1229

INTRODUCTION

Dental caries is the most common chronic disease of childhood. Twenty-four percent of US children 2 to 4 years of age, 53% of children 6 to 8 years of age, and 56% of 15-year-olds have caries experience (ie, untreated dental caries, filled teeth, teeth missing as a result of dental caries).¹ For children 5 to 19 years of age, children from poor and racial or ethnic minority families have higher rates of untreated dental caries than do their peers from nonpoor and nonminority families.² For some age groups, the incidence of dental caries has decreased or stayed the same, but for the youngest children, it has increased.³ Among 6- to 8-year-olds and 15-year-olds, caries experience and untreated dental decay remained mostly unchanged between 1988–1994 and 1999–2004.¹ In children 2 to 4 years of age, the caries experience increased significantly, from 19% to 24%, during that same time period. The increase in the caries experience and untreated caries was statistically significant in children from poor families.

THE ETIOLOGY AND PATHOGENESIS OF DENTAL CARIES

A dynamic process takes place at the surface of the tooth that involves constant demineralization and remineralization of the tooth enamel (the caries balance).^{4,5} Multiple factors affect that dynamic process and can be manipulated in ways that tip the balance toward disease (demineralization) or health (remineralization). These factors include bacteria, sugar, saliva, and fluoride. Because these factors can be

manipulated, it is possible for pediatricians and families to prevent, halt, or even reverse the disease process. Different oral structures and tissues have different and distinct microbial communities (microbiomes).⁶ The oral microbiome at the surface of the tooth is referred to as dental plaque. During the disease process of dental caries, bacteria that are aciduric and acidogenic predominate in the dental plaque. *Streptococcus mutans* is most strongly associated with dental caries, although other bacterial species have these capabilities and thus can also be pathogenic. When environmental factors make it possible to select for these pathogenic bacteria in dental plaque, the disease process begins.

A key environmental factor that allows for selection and proliferation of these pathogenic bacteria is dietary sugar intake. Because these pathogenic bacteria have the ability to ferment sugars, produce acid, and decrease the pH of the dental plaque, they make possible the selection of other aciduric, acidogenic bacteria that will contribute to disease. As more bacteria produce more acid, the pH at the surface of the tooth decreases. This process causes the demineralization of the tooth enamel. Unimpeded, these long periods of low pH and demineralization will result in cavitation.

Saliva is an important factor in buffering the low pH and bringing these demineralization pressures back to a balance with remineralization. In addition to acting as a buffering agent, saliva also flushes the oral cavity of food particles and provides an environment rich in calcium and phosphate to aid in remineralization. When salivary flow is impeded, the pH is able to decrease to a lower level, tipping the scales toward demineralization (disease); in addition, the time it takes to buffer back to a normal pH is longer.⁷

Another important factor that can affect the balance of demineralization

and remineralization is fluoride. More in-depth reviews of fluoride are available elsewhere.^{8–10} It is important, however, for pediatricians and other child health care providers to understand how fluoride influences the caries balance. Fluoride has 3 key effects on the caries balance: (1) inhibition of demineralization at the tooth surface; (2) enhancement of remineralization, which results in a more acid-resistant tooth surface; and (3) inhibition of bacterial enzymes.¹¹ The primary effect of fluoride is topical, via fluoridated toothpastes, mouth rinses, and varnishes, although there is still value in systemic fluoride exposures via fluoridated water and supplements.^{9,11}

PREVENTIVE STRATEGIES

Caries Risk Assessment

Ideally, primary prevention efforts will anticipate and prevent caries before the first sign of disease. Preventive strategies for this multifactorial, chronic disease require a comprehensive and multifocal approach that begins with caries risk assessment. Assessing each child's risk of caries and tailoring preventive strategies to specific risk factors are necessary for maintaining and improving oral health. There is no single test that takes into consideration all risk factors and accurately predicts an individual's susceptibility to caries. However, pediatricians can conduct an excellent risk assessment for caries by focusing on the key risk factors for dental caries that are associated with diet, bacteria, saliva, and status of the teeth (both current status and previous caries experience). The American Academy of Pediatrics (AAP)/Bright Futures Oral Health Risk Assessment Tool can be found at <http://www2.aap.org/oralhealth/RiskAssessmentTool.html>.¹²

Sugars (but not sugar substitutes) are a critical risk factor in the development of caries. The risk of caries is greatest if sugars are consumed at high frequency and are in a form that

remains in the mouth for long periods of time.¹³ Thus, key behaviors that place a child at high risk of caries include continual bottle/sippy cup use (especially with fluids other than water), sleeping with a bottle (especially with fluids other than water), frequent between-meal snacks of sugars/cooked starch/sugared beverages, and frequent intake of sugared medications.

Early acquisition of *S mutans* is a major risk factor for early childhood caries and future caries experience.¹⁴ Strong evidence demonstrates that mothers are a primary source of *S mutans* colonization for their children.¹⁵ Thus, an important factor associated with caries risk in young children is the recent or current presence of active dental decay in the primary caregiver. Prevention, diagnosis, and treatment of oral diseases are highly beneficial, can be undertaken, and should be encouraged during pregnancy with no additional fetal or maternal risk compared with the risk of not providing care.¹⁶ The most important and predictive risk factor for caries, however, is previous caries experience. This finding is not surprising, considering that the factors which initiated the disease process often continue to exist over time.

Other caries risk factors are associated with salivary flow and the status of the teeth. Diseases (eg, diabetes mellitus, Sjögren's syndrome, cystic fibrosis) and medications (eg, antihistamines, anticonvulsants, antidepressants) that result in xerostomia (decreased salivary flow) reduce the availability of saliva to buffer the acid produced by pathogenic bacteria, thus enhancing their ability to cause damage to the teeth. In addition, the teeth of preterm infants, which frequently have enamel defects, are at increased susceptibility for disease. Older children who have deep pits and fissures in their molars are also at increased susceptibility for disease.

Anticipatory Guidance

With a clear understanding of the etiology of dental caries and the risk factors that lead to and facilitate the spread of this disease, pediatricians can target anticipatory guidance to assist families in preventing it. Because the disease of dental caries is multifocal, the anticipatory guidance should also be multifocal. Pediatricians should concentrate their anticipatory guidance on topics that can affect the risk of disease.

Dietary Counseling

Because sugar intake is such an important risk factor for dental caries, pediatricians can incorporate anticipatory guidance associated with preventing dental caries into discussions with families about dietary habits and nutritional intake. Pediatricians should counsel parents and caregivers on the importance of reducing the frequency of exposure to sugars in foods and drinks. To decrease the risk of dental caries and ensure the best possible health and developmental outcomes, pediatricians should recommend that parents do the following:

- Exclusively breastfeed infants for 6 months and continue breastfeeding as complementary foods are introduced for 1 year or longer, as mutually desired by mother and infant.¹⁷
- Discourage putting a child to bed with a bottle. Establish a bedtime routine conducive to optimal oral health (eg, brush, book, and bed).
- Wean from a bottle by 1 year of age.
- Limit sugary foods and drinks to mealtimes.
- Avoid carbonated, sugared beverages and juice drinks that are not 100% juice.
- Limit the intake of 100% fruit juice to no more than 4 to 6 oz per day.
- Encourage children to drink only water between meals, preferably fluoridated tap water.

- Foster eating patterns that are consistent with guidelines from the US Department of Agriculture.

Oral Hygiene

The value of good oral hygiene lies in controlling the levels and activity of disease-causing bacteria in the oral cavity and delivering fluoride to the surface of the tooth. It is important to remember that pathogenic bacteria can be passed from caregiver to child.¹⁸ Thus, anticipatory guidance for both parent and child is important. Key anticipatory guidance points regarding oral hygiene are as follows:

- Parents/caregivers should be encouraged to model and maintain good oral hygiene and a relationship with their own dental provider.
- Parents/caregivers, especially those with significant history of dental decay, should be cautioned to avoid sharing with their child items that have been in their own mouths.
- The child's teeth should be brushed twice a day as soon as the teeth erupt with a smear or a grain-of-rice-sized amount of fluoridated toothpaste. After the third birthday, a pea-sized amount should be used.
- Parents/caregivers should help/supervise a child brushing his or her teeth until mastery is obtained, usually at around 8 years of age.

Fluoride

The delivery of fluoride to the teeth includes community-based options (water fluoridation), self-administered modalities (fluoride toothpaste and supplements), and professional applications (fluoride varnish). Each of these delivery mechanisms is useful in preventing dental caries.

Water fluoridation is a community-based intervention that optimizes the level of fluoride in drinking water, resulting in preeruptive and posteruptive protection of the teeth.¹⁹ Water fluoridation is a

cost-effective means of preventing dental caries, with the lifetime cost per person equaling less than the cost of 1 dental restoration.^{20,21} Most bottled waters do not contain an adequate amount of fluoride.

Fluoride toothpaste is an important way to deliver fluoride to the surface of the tooth. Fluoride toothpaste has been shown to be effective in reducing dental caries in both primary and permanent teeth.^{22,23} It is important to limit the amount of toothpaste used to a smear or a grain-of-rice-sized amount for young children and no more than a pea-sized amount for children older than 3 years.²⁴ Fluoride supplements should be prescribed for children whose primary source of drinking water is deficient in fluoride.²⁵

Fluoride varnish is a professionally applied, sticky resin of highly concentrated fluoride. Two or more applications of fluoride varnish per year are effective in preventing caries in children at high risk of all ages.⁸ In most states, pediatricians can apply and be paid for application of fluoride varnish to the teeth of young children. Application of fluoride varnish is even more effective when coupled with counseling.²⁶ The US Preventive Services Task Force recently published a new recommendation that primary care clinicians apply fluoride varnish to the primary teeth of all infants and children starting at the age of primary tooth eruption (B recommendation).²⁵ More details and recommendations on fluoride can be found in the AAP clinical report "Fluoride Use in Caries Prevention in the Primary Care Setting."¹⁰

Other Important Anticipatory Guidance Topics

A frequent topic of discussion with parents is nonnutritive oral habits, such as use of pacifiers and thumb sucking. AAP policy states that parents consider offering a pacifier at naptime

and bedtime because of a protective effect of pacifiers on the incidence of sudden infant death syndrome after the first month of life.²⁷ Both finger- and pacifier-sucking habits will only cause problems with dental structures if they go on for a long period of time. Evaluation by a dentist is indicated for non-nutritive sucking habits that continue beyond 3 years of age.²⁸

Dental injuries are common. Twenty-five percent of all schoolchildren experience some form of dental trauma.²⁹ Pediatricians can help prevent such trauma by encouraging parents to cover sharp corners of household furnishings at the level of walking toddlers, recommend use of car safety seats, and be aware of electrical cord risk for mouth injury. Pediatricians can also encourage mouthguard use during sports activities in which there is a significant risk of orofacial injury.³⁰ More information on dental trauma is available in the AAP clinical report "Management of Dental Trauma in a Primary Care Setting."³¹

COLLABORATION WITH DENTAL PROVIDERS

The AAP, the American Academy of Pediatric Dentistry, the American Dental Association, and the American Association of Public Health Dentistry all recommend a dental visit for children by 1 year of age. Although pediatricians have the opportunity to provide early assessment of risk for dental caries and anticipatory guidance to prevent disease, it is also important that children establish a dental home. A dental home is the ongoing relationship between the dentist and the patient, inclusive of all aspects of oral health care delivered in a comprehensive, continuously accessible, coordinated, and family-centered way.³²

Unfortunately, little is known about pediatric health care providers' dental referral behaviors and patterns. Al-

though 1 study found that children 2 to 5 years of age who received a recommendation from their health care provider to visit the dentist were more likely to have a dental visit,³³ the US Preventive Services Task Force found no study that evaluated the effects of referral by a primary care clinician to a dentist on caries incidence.³⁴ It is also noteworthy that preschool-aged children covered by Medicaid who had an early preventive dental visit by 1 year of age were more likely to use subsequent preventive services and to have lower dental expenses.³⁵

With early referral to a dental provider, there is an opportunity to maintain good oral health, prevent disease, and treat disease early. Establishing such collaborative relationships between physicians and dentists at the community level is essential for increasing access to dental care for all children and improving their oral and overall health.

CONCLUSIONS

Oral health is an integral part of the overall health and well-being of children.³⁶ A pediatrician who is familiar with the science of dental caries, capable of assessing caries risk, comfortable with applying various strategies of prevention and intervention, and connected to dental resources can contribute considerably to the health of his or her patients. This policy statement, in conjunction with the oral health recommendations of the third edition of the AAP's *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents*, serves as a resource for pediatricians and other pediatric primary care providers to be knowledgeable about addressing dental caries.³⁷ Because dental caries is such a common and consequential disease process in the pediatric population, it is essential that pediatricians include oral health in their daily practice of pediatrics.

SUGGESTIONS FOR PEDIATRICIANS

1. Administer an oral health risk assessment periodically to all children.
2. Include anticipatory guidance for oral health as an integral part of comprehensive patient counseling.
3. Counsel parents/caregivers and patients to reduce the frequency of exposure to sugars in foods and drinks.
4. Encourage parents/caregivers to brush a child's teeth as soon as teeth erupt with a smear or a grain-of-rice-sized amount of fluoride toothpaste and a pea-sized amount at 3 years of age.
5. Advise parents/caregivers to monitor brushing until 8 years of age.
6. Refer to the AAP clinical report, "Fluoride Use in Caries Prevention in the Primary Care Setting," for fluoride administration and supplementation decisions.
7. Build and maintain collaborative relationships with local dentists.
8. Recommend that every child has a dental home by 1 year of age.

CLINICAL REPORT

Management of Dental Trauma in a Primary Care Setting

abstract

FREE

The American Academy of Pediatrics and its Section on Oral Health have developed this clinical report for pediatricians and primary care physicians regarding the diagnosis, evaluation, and management of dental trauma in children aged 1 to 21 years. This report was developed through a comprehensive search and analysis of the medical and dental literature and expert consensus. Guidelines published and updated by the International Association of Dental Traumatology (www.dental-traumaguide.com) are an excellent resource for both dental and non-dental health care providers. *Pediatrics* 2014;133:e466–e476

INTRODUCTION

By 14 years of age, 30% of children have experienced a dental injury.¹ Many of these children are taken directly to their medical home, an urgent care center, or an emergency department for evaluation and treatment. Few of these facilities employ a dentist; therefore, the primary care provider for the injured child will most likely be a pediatrician or other physician. In many instances, the injured tooth's survival is time-dependent. Therefore, it is imperative for the pediatrician to manage the acute dental injury properly to afford the child's dentition the best possible outcome. Pediatricians can also advocate for dental injury–preventive measures, as they provide other injury-prevention messages for caregivers of children and preparticipation sports physicals.

DENTAL TRAUMA PREVENTION

Pediatricians can advocate for dental injury–preventive measures as they provide other injury-prevention messages during well-child visits. Caregivers should be counseled about participation in sports and activities that are appropriate for the child's age and development, general household safety measures such as stairway gates and removal of trip hazards, and adult supervision of activities that could lead to dental trauma. Although these measures will not prevent all dental injuries, they can reduce their incidence and severity.

As part of a preparticipation sports physical, physicians should recommend sports mouth guards to prevent sports-related mouth injuries. Currently, the US National Collegiate Athletic Association requires mouth guards for 4 sports (ice hockey, lacrosse, field hockey,

and football).² The American Dental Association recommends the use of mouth guards in 29 sports/exercise activities. Sports mouth guards can be made of a variety of materials: polyvinyl acetate-polyethylene or ethylene vinyl acetate copolymer, polyvinyl-chloride, latex rubber, or polyurethane. Mouth guards can be custom made in the dental office from an impression of the patient's maxillary arch and can also be purchased, typically in a store that carries sports-related items. Purchased mouth guards can be customized by boiling the mouth guard to soften the material and then biting into the mouth guard to create an impression of the upper teeth, which helps create a better fit. Stock mouth guards can also be purchased, but they are not as well adapted to the teeth. Impact studies have shown that wearing any type of mouth guard reduces the risk of tooth injury compared with not wearing a mouth guard.

DENTAL TRAUMA ASSESSMENT

For all dental injuries, it is important to follow a systematic approach.³ Before initiating treatment, an abbreviated medical and dental history should be obtained to gain information vital to urgent care. Questions with respect to how, when, and where the dental injury occurred are important for determining the need for a tetanus booster, the possibility of child abuse, and the possibility of a head injury.⁴ Physicians have the legal obligation to explore and report reasonable suspicions of child abuse. Given the proximity of the dentition to the cranium, it is important to complete an age-appropriate neurologic assessment, which may include inquiring whether the child experienced loss of consciousness, dizziness, headache, or nausea and vomiting. If a concussion or a more severe intracranial injury is suspected, then protection of the cervical spine and

immediate medical evaluation should be prioritized.⁵ Specific to the teeth, disturbances in the occlusion (bite) should be assessed because this may reveal a displaced tooth or an alveolar or jaw fracture. Lastly, inquiring about tooth sensitivity or pain to hot and/or cold exposures may indicate that the dentin and/or pulp tissue are exposed, requiring immediate referral to a dentist.

The clinical examination should include thorough evaluation of the face, lips, and oral musculature for soft tissue lesions. To facilitate an accurate extraoral and intraoral examination, the face and oral cavity should be cleansed with water or saline. The facial skeleton should be palpated for signs of fractures. The dental trauma region should be inspected for fractures, abnormal tooth position, and tooth mobility. Identifying whether the injured tooth is a primary versus a permanent tooth is important in the management of certain types of dental injuries. In general, children younger than 5 years are in the primary dentition (Fig 1).^{*} The 20 primary teeth are named alphabetically starting with tooth A in the upper right posterior quadrant. From ages 6 through 12 years, children are in the mixed dentition in which they are exchanging the primary teeth for the permanent teeth. After 8 or 9 years of age, most of the incisors are permanent teeth, with a mixture of primary canines and molars until the age of 12 years. By 13 years of age, most children have exfoliated all of their primary teeth and have 28 permanent

teeth. The permanent teeth follow a numbering system (Fig 2). Discussion with the parent/caregiver as to whether the child has lost any primary teeth from natural exfoliation can help identify whether the child is in full primary dentition or mixed dentition. Primary incisor teeth are considerably smaller in size than permanent teeth. Physicians can use their own dentition as a point of reference to estimate the size of permanent teeth for comparative purposes. In addition to proper tooth identification, the direction of any tooth displacement as well as any pulp involvement should be noted. Familiarity with tooth anatomy will assist in determining the extent of injury present (Fig 3).

After the initial clinical assessment and administration of first aid, the injured region should be examined with the most appropriate radiographic techniques. Radiographic assessment of an injured tooth is best accomplished with conventional intraoral dental radiographs instead of computed tomography (CT). There is considerably less radiation involved with conventional intraoral dental radiographs than with a head CT scan. Several clinical studies have demonstrated that multiple dental radiographs from different angulations are needed to detect displacement of the tooth in its socket as well as presence of root fractures.^{6,7} If a lip laceration is present, an intraoral soft tissue radiograph may be indicated to visualize any foreign bodies, including tooth fragments. These types of radiographs are more feasibly obtained by a dentist because a general emergency department or radiologist's facility may not be equipped to perform radiography, and a dentist's evaluation may be required to order the correct radiographic studies. If a maxillary or mandibular fracture is suspected, a panoramic film, cone-beam CT, or CT scan may be indicated. For all

radiograph selections with dental trauma, the safety principle of ALARA (as low as reasonably achievable) should be followed to minimize exposure to radiation.⁸

If possible, and with appropriate informed consent, digital photographic documentation of the trauma is helpful because it offers an exact documentation of the extent of injury and can be sent electronically to a consulting dentist for guidance in managing the acute phase of treatment. Photographs can also be used later to facilitate any legal or insurance claims related to the injury.

With the combined information from the clinical and radiographic examinations, a diagnosis can be made, and treatment can be planned. The man-

agement of dental trauma is described here in 2 parts: trauma involving the primary dentition and trauma involving the permanent dentition. Depending on the type of dental injury, there can be distinct differences in how a primary tooth is managed compared with a permanent tooth.

DENTAL TRAUMA CLASSIFICATIONS

Concussion

A concussed tooth is tender to touch, but there is no increased mobility or displacement. There is no sulcular bleeding (at the margin of the tooth and gums).

Subluxation

A subluxated tooth presents with abnormal mobility but no displacement. Sulcular bleeding is present (Fig 4).

Lateral Luxation

Clinically, a luxated tooth is displaced laterally, most often in a palatal/lingual direction (Fig 5). The injured tooth may be mobile or firmly locked into the displaced position.

Extrusive Luxation

Partial vertical displacement of the injured tooth from its socket is classified as an extrusive luxation injury or a partial avulsion (Fig 6).

Intrusive Luxation

In this type of luxation, the tooth is forced into the alveolus and usually locked without any mobility (Fig 7). The tooth appears shortened. In cases of severe intrusion, the tooth may appear to be missing. Bleeding from the gingival sulcus is present.

Avulsion

An avulsion is the complete displacement of the tooth out of the socket (Fig 8). The periodontal ligament is severed, and the alveolus may be fractured.

FIGURE 4
Subluxation.

FIGURE 5
Lateral luxation.

FIGURE 6
Extrusive luxation.

Infraction (Crack)

An infraction is a crack or craze line in the surface of the enamel. The tooth appears intact, but crack lines may be visualized by shining a focused source of light, such as the otoscope, onto the crown of the tooth in an axial direction.

Enamel Only (Uncomplicated) Crown Fracture

If the fracture of the tooth is contained within the enamel layer only, it is considered to be an uncomplicated fracture. There is generally limited sensitivity associated with this type of injury unless there is a rough edge

that is causing irritation to the tongue or lips.

Enamel and Dentin (Uncomplicated) Crown Fracture

If the fracture of the tooth is contained within the enamel and dentin layers without exposure of the pulpal tissues, then the injury is classified as an uncomplicated fracture of enamel and dentin. When the dentin is exposed, there is frequently sensitivity associated with exposure to air, food, or beverages (Fig 9).

Crown Fracture With Exposed Pulp (Complicated)

If the fracture of the tooth exposes the pulpal tissue, the injury is classified as a complicated fracture. Crown fractures with exposed pulp are frequently sensitive and introduce an increased risk of infection because the pulp tissue is exposed to the oral flora (Fig 10). In severe fractures, the root may be involved, creating a crown-root fracture (Fig 11).

Root Fracture

When the crown segment of an injured primary incisor displays mobility, there is a risk of a root fracture. This can only be verified with an intraoral dental radiograph (Fig 12).

Alveolar Fracture

Dislocation of several teeth that move together when palpated suggests that there is a fracture of the alveolus (Fig 13).

PRIMARY DENTAL TRAUMA EPIDEMIOLOGY AND MANAGEMENT

Epidemiology

In children 0 to 6 years of age, oral injuries are ranked as the second most common injury, accounting for

FIGURE 7
Intrusive luxation.

FIGURE 8
Avulsion.

FIGURE 9
Uncomplicated crown fracture (no pulp exposure).

almost 20% of all bodily injuries.⁹ The greatest incidence of trauma to the primary teeth occurs at 2 to 3 years of age, when motor coordination is developing.^{10,11} The most common teeth injured in the primary dentition are the maxillary incisors. These teeth are typically present in the mouth from 12 months to 6 years of

age. Exfoliation of the maxillary incisors may vary from 5 to 7 years of age. The most common dental injury to the primary dentition is a luxation.¹⁰ Dental injuries in the primary dentition occur more often in boys. Child abuse should be considered as a possible etiology in any child younger than 5 years with trauma

affecting the lips, gingiva, tongue, palate, and severe tooth injury.^{12,13}

Concussion

No immediate treatment is indicated for a dental concussion. Observing the injured tooth for possible future pulpal necrosis is recommended. Pulpal necrosis in a primary tooth may cause the tooth to appear gray in color or to have a parulis (gingival abscess or gum boil) on the gingiva adjacent to the root of the affected tooth. If tooth discoloration or a localized parulis forms, then referral to a dentist within a few days is recommended.

Subluxation

No immediate treatment is indicated for a subluxated primary tooth. The injured primary tooth should be followed for possible future pulpal necrosis (as described previously). If tooth discoloration develops or a localized parulis appears, then referral to a dentist within a few days is recommended. If more extensive gingival or facial swelling develops, then immediate referral to a dentist is recommended.

Lateral Luxation

If the tooth displacement is minor, then gentle repositioning is indicated, or acceptance of the position as spontaneous repositioning will take place. For more severe displacement injuries, the child's ability to bite teeth together may be affected. It is important to ensure that the tooth position does not interfere with the occlusion (bite). Asking the child to say "cheese" or the letter "e" allows one to visualize the occlusion and determine whether the luxated tooth is interfering with the complete closure of the bite. If the child is unable to bite the teeth

FIGURE 10
Complicated crown fracture (pulp exposure).

FIGURE 11
Crown root fracture.

FIGURE 12
Root fracture.

together, then the tooth will need to be repositioned by the urgent care provider, or the child should be im-

mediately referred to a dentist. It is important to ensure that the posterior teeth (molars) are able to fully

interdigitate and masticate food properly. If the luxated tooth is near exfoliation and interfering with the bite, then extraction of the injured tooth is indicated. Immediate referral to a dentist is recommended.

Extrusive Luxation

If the extrusion is minor, then gentle repositioning is indicated. In severe extrusive injuries (>3 mm), extraction is indicated. Immediate referral to a dentist is recommended.

Intrusive Luxation

When a primary tooth is intruded, it will typically reerupt without intervention. In cases of severe intrusion, an intraoral radiograph is indicated to determine the location or absence of the injured tooth. In rare circumstances, the tooth may become ankylosed (fused to bone) and require extraction to prevent blocking of the eruption of the permanent successor. Observation is indicated for all intruded primary incisors. Immediate referral to a dentist is indicated for more severe intrusions or to rule out avulsion of the tooth. With any intruded primary tooth, there is a potential for damage to the developing permanent tooth germ.

Avulsion

When a primary tooth is avulsed and the tooth was found, there is no treatment indicated. An avulsed primary tooth should not be replanted to avoid damage to the underlying permanent tooth germ.⁸ If the tooth is not found, clinical and radiographic examination can confirm that the tooth is not intruded. A chest radiograph may be indicated if the child displays breathing difficulties to ensure the tooth was not aspirated. The subsequent avulsion site will need to be monitored for healing and potential space loss. If the child has an active digit-sucking habit and avulses

FIGURE 13
Alveolar fracture.

a maxillary incisor, the potential for space loss in the upper anterior region exists. An appliance with an artificial tooth may be indicated to prevent space loss.¹⁴ Therefore, referral to a dentist within a few days is recommended to provide space management.

Infraction (Crack)

If the primary tooth sustains a marked crack in the enamel without loss of tooth structure, then placing a resin sealant over the infraction line may be indicated to avoid obvious staining of the line. In many cases, no treatment is indicated; however, the tooth should be monitored for signs of pulpal necrosis until exfoliation.

Enamel Only (Uncomplicated) Crown Fracture

If the fracture of the primary tooth is contained within the enamel surface only, then the tooth fracture area can be smoothed with a dental handpiece and polishing bur or left untreated if the fracture site is smooth to touch. This is best accomplished by a dentist and does not require immediate attention unless there is a sharp edge causing soft tissue injury. The tooth should be monitored by a dentist for signs of pulpal necrosis until exfoliation.

Enamel and Dentin (Uncomplicated) Crown Fracture

A primary tooth with an uncomplicated fracture involving enamel and dentin can be restored with tooth-colored dental material. A referral to a dentist within a few days is indicated; if the child's behavior precludes dental restorative care, then the tooth fracture area can be smoothed with a dental handpiece and polishing bur or left untreated if the fracture site is smooth to touch. The tooth should be monitored by a dentist for signs of pulpal necrosis until exfoliation.

Crown Fracture With Exposed Pulp (Complicated)

If the fracture of the primary tooth exposes the pulpal tissue, then a pulpotomy or pulpectomy and restorative care is indicated. If the child's behavior precludes pulp therapy and dental restorative care, then extraction of the traumatized primary tooth is indicated. If the tooth is treated, then it will need to be monitored for signs of pulpal necrosis until exfoliation. With severe crown fractures, the root may also be involved. If a crown root fracture is suspected, an intraoral periapical radiograph should be obtained to determine the extent of injury to the tooth and root. Extraction of the tooth is indicated if the fracture extends onto the root surface. Immediate referral to

a dentist is indicated for a tooth with a complicated fracture. If the tooth is removed, then a space maintainer may be indicated if the child has an active digit-sucking habit.

Root Fracture

If a root fracture of a primary tooth is suspected because of excessive tooth mobility, then referral to a dentist for a radiographic examination is indicated. The timing of the referral to the dentist is dependent on the amount of crown mobility. If there is concern for aspiration of the crown portion, then immediate referral to a dentist is indicated; subsequent management of the injured tooth is dependent on the location of the root fracture. The closer the root fracture is to the apex of the root, the better the prognosis. This type of root fracture rarely requires treatment. Conversely, the closer the root fracture is to the crown of the tooth, the poorer the prognosis. The crown segment is usually removed, and if the primary root can be removed without damaging the underlying permanent tooth bud, then it can also be extracted. If removal of the root poses a risk to the developing permanent tooth bud, then the residual root can be left and monitored for natural resorption.

Alveolar Fracture

If the trauma involves a fracture of the alveolar bone displayed by dislocation of several teeth that move together, then reposition of the segment and stabilization with a splint is indicated. Immediate referral to a dentist or an oral surgeon is recommended.

Sequelae From Dental Trauma in the Primary Dentition

To optimize the best healing results from trauma sustained by the primary dentition, parents and caregivers should be advised about the

importance of good oral hygiene practices and injury prevention. For the first 10 days after an injury to a primary tooth, the child should eat a soft diet, and sucking on a pacifier or digit should be restricted, if possible.⁹ The routine use of systemic antibiotics in the postoperative care of primary tooth trauma is not indicated.⁹ However, the child's medical condition may require antibiotic coverage. Parents/caregivers should be advised about the potential for crown discoloration, pulp canal obliteration, or pulpal necrosis. Children may not report painful symptoms from a necrotic tooth; therefore, parents/caregivers should be vigilant regarding the development of the symptoms of pulpal necrosis: gingival swelling, increased mobility, and/or parulis. If any of these symptoms develop, the parent/caregiver should obtain follow-up care with the child's dentist to determine the need for extraction of the previously injured tooth.

PERMANENT DENTAL TRAUMA EPIDEMIOLOGY AND MANAGEMENT

Epidemiology

A 12-year review of the scientific literature reports that 25% of all school-age children experience some form of dental trauma.¹⁵ The most common injury reported in the permanent dentition is an uncomplicated crown fracture involving the maxillary incisors. Injuries to permanent teeth are most often caused by falls, followed by automobile crashes, violence, and sports.¹⁶ Sports-related accidents account for 10% to 39% of all dental injuries in children.¹⁷ During sporting activities, falls, collisions, contact with hard surfaces, and contact with sports-related equipment place the child at risk for oral facial injury. Boys sustain more dental injuries to their permanent teeth than girls. During the adolescent years, the possibility of abuse exists and should be

considered in assessing the cause of dental trauma.

Concussion

No treatment is indicated for a concussed permanent tooth. Observing the injured tooth for possible future pulpal necrosis is recommended.

Subluxation

No treatment is indicated for a subluxated permanent tooth. The injured permanent tooth should be followed for possible future pulpal necrosis.

Lateral Luxation

For any amount of displacement, it is important to reposition the tooth to its original position. If the displacement is minor, then gentle digital apical pressure to reposition the tooth is indicated. For more significant displacement, dental forceps may need to be used to reposition the tooth in the proper socket position requiring immediate referral to a dentist. It is important to ensure that the tooth position does not interfere with the occlusion (bite). Asking the child to say "cheese" or the letter "e" allows one to visualize the occlusion and to ensure that the posterior teeth (molars) are able to fully interdigitate and masticate food properly. The permanent tooth will need to be stabilized with a flexible splint for 4 weeks. The tooth should be followed for possible periodontal and pulpal pathology. After severe permanent tooth luxation, it is possible that the tooth will require root canal treatment.

Extrusive Luxation

If the extrusion is minor, gentle digital pressure to reposition the tooth into the socket is indicated. Immediate referral to a dentist for placement of a flexible splint if the tooth remains mobile after repositioning is recommended. If the extrusion is excessive,

then repositioning with dental forceps may be indicated, requiring immediate referral to a dentist. After repositioning, the tooth should be stabilized with a flexible splint for 2 weeks. The dentist will determine the need for pulp therapy depending on the maturity of the root.

Intrusive Luxation

In cases of mild intrusion, the tooth will typically reerupt gradually on its own. Bleeding from the gingival sulcus is present. If no reeruption is visible after a few weeks, orthodontic or surgical repositioning of the intruded tooth is necessary. Early involvement of a dentist is important to supervise the repositioning of the intruded incisor. In severe intrusion cases, the tooth may not be visible clinically, requiring intraoral radiography to be performed to assess the position of the tooth within the alveolus. In rare circumstances, the intruded tooth may become ankylosed (fused to bone) and require extraction to prevent warping of the alveolar ridge, followed by placement of an artificial tooth.

Avulsion

Avulsion of a permanent tooth is the most serious of all dental injuries.¹⁸ The prognosis of the permanent tooth depends on measures taken immediately after the accident. The treatment of choice is immediate replantation. After the tooth is located, it should be handled by the crown portion only and not the root because the root is covered in fragile fibroblasts important for reattachment to the alveolus. Before replantation, it should be confirmed that the avulsed tooth is a permanent tooth; primary teeth should not be replanted. If the permanent tooth is dirty, it should be washed briefly (10 seconds) under cold running water and repositioned

in the socket. The patient/parent should be encouraged to replant the tooth at the site of the injury. The child should be instructed to bite on a cloth to hold it in position until he or she can get to the doctor's office or emergency department. If this is not possible, the tooth should be placed in a suitable storage medium (eg, a glass of cold milk or balanced salt solution, if available). If no storage media are accessible, then the patient can drool saliva into a container and use that as a transport medium. Storing an avulsed tooth in water should be avoided because water causes osmotic lysis of the root fibroblasts. After the tooth has been replanted or placed in a proper storage medium, dental care should be obtained immediately. A flexible splint will need to be placed by the dentist for up to 2 weeks. Most teeth will require root canal therapy, which will need to be instituted within 7 to 10 days after replantation. The tooth should be monitored for the potential of bodily rejection in the form of root resorption. Systemic antibiotics are indicated after reimplantation of an avulsed permanent tooth. For children older than 12 years, doxycycline is the recommended antibiotic, and for children younger than 12 years, penicillin is indicated. For children who are allergic to penicillin, clindamycin is recommended.

Infraction (Crack)

If the permanent tooth sustains a marked crack in the enamel without loss of tooth structure, then placing a resin sealant over the infraction line may be indicated to avoid obvious staining of the line.

Enamel Only (Uncomplicated) Crown Fracture

If the fracture of the permanent tooth is contained within the enamel layer only, then the tooth fracture area can be smoothed with a dental handpiece

and polishing bur or left untreated if the fracture site is smooth to touch. There is generally little or no sensitivity associated with fractures involving enamel, so immediate referral to a dentist is not necessary. The tooth should be monitored for signs of pulpal necrosis.

Enamel and Dentin (Uncomplicated) Crown Fracture

If the fracture of the permanent tooth is contained within the enamel and dentin surfaces without exposure of the pulpal tissues, then the tooth can be restored with tooth-colored dental material, or if the tooth fragment is available, it can be rebonded to the tooth. When dentin is exposed, there may be tooth sensitivity, and the patient should be referred to a dentist within a few days. The more sensitive the tooth is, the more expediently the patient should be seen by a dentist to cover the exposed dentin and reduce the discomfort. By covering the exposed dentin, the risk of pulpal bacterial contamination is reduced. The tooth should be monitored for signs of pulpal necrosis.

Crown Fracture With Exposed Pulp (Complicated)

If the fracture of the permanent tooth exposes the pulpal tissue, then appropriate pulp therapy should be rendered by a dentist immediately to preserve pulp vitality (Fig 10).¹⁵ The timeliness of pulp therapy is important in the young permanent tooth. The permanent tooth is considered immature until 3 years after eruption. If the tooth is immature, then it will need to be monitored for signs of continued root development and the lack of pulpal necrosis. If the tooth has a mature root, then root canal therapy is usually the treatment of choice. In severe cases, the fracture line can involve the root—hence, it is known as a crown-root fracture. The crown fragment must be removed, and

the health of the remaining fragment must be determined. In some cases, the remaining fragment can be orthodontically extruded and subsequently restored with a full-coverage crown, or the remaining root can be submerged to maintain the alveolar bone for a future implant. For esthetics and space maintenance, the missing crown can be replaced by an orthodontic retainer with a prosthetic tooth or by creating a temporary bridge using the original crown fragment.

Root Fracture

When the crown segment of an injured permanent incisor displays mobility, referral to a dentist for a radiographic examination is indicated to rule out a root fracture. The subsequent management of the injured tooth is dependent on the location of the root fracture. The closer the root fracture is to the apex of the root, the better the prognosis. This type of root fracture rarely requires treatment. Conversely, the closer the root fracture is to the crown of the tooth, the poorer the prognosis. Splinting is recommended for 4 weeks. If crown segment remains mobile after splinting, then the crown segment is removed, and the residual root can be orthodontically extruded, treated with root canal therapy, and restored.

Alveolar Fracture

If the trauma involves a fracture of the alveolar bone displayed by dislocation of several teeth that move together, then reposition of the segment and stabilization with a splint is indicated. Immediate referral to a dentist or an oral surgeon for repositioning and placement of a stabilization wire is indicated.

Sequelae From Dental Trauma in the Permanent Dentition

To optimize the best healing results from trauma sustained by the permanent dentition, parents and caregivers should

be advised on the importance of good oral hygiene practices and injury prevention. For the first 10 days after an injury to a permanent tooth, the child should eat a soft diet, and digit sucking should be restricted, if possible.^{15,18} The routine use of systemic antibiotics in the postoperative care of dental trauma is not indicated (except in cases of permanent tooth avulsion and reimplantation).⁹ The child's medical history may require antibiotic coverage. Parents/caregivers should be advised about the potential for crown discoloration, root resorption, ankylosis, or pulpal necrosis. Parents/caregivers and the child should be vigilant regarding the development of the symptoms of pulpal and periodontal abnormalities subsequent to the dental injury: crown discoloration, gingival swelling, increased mobility, and/or sinus tract (parulis). If any of these symptoms develop, the parent/caregiver should obtain follow-up care with the child's dentist to determine the need for additional treatment of the previously injured tooth.

CONCLUSIONS

This clinical report provides evidence-based recommendations for the management of dental trauma in children 1 to 21 years of age. When dental trauma cannot be avoided through the use of preventive measures, it emphasizes the importance of proper diagnosis, treatment planning, and follow-up care conducive to a favorable outcome for an injured tooth in a pediatric patient. The report provides decision-making strategies to assist pediatricians and other primary care physicians in diagnosing and managing children who experience dental trauma. Table 1 provides a concise summary of this information. Close collaboration between the medical and dental home are also important

TABLE 1 Dental Treatment Plan for Traumatic Injuries in the Primary and Permanent Dentition

Description	Primary Dentition	Permanent Dentition
Concussion/subluxation	Observe, soft foods for 1 wk, dental radiograph to rule out root fracture	Observe, soft foods for 1 wk, dental radiograph to rule out root fracture
Luxation	Reposition tooth or extract, do not splint	Dental radiograph, reposition tooth, splint for 4 wk
Extrusion	Reposition tooth or extract, do not splint	Dental radiograph, reposition tooth, splint for 2 wk
Intrusion	Dental radiograph, observe and allow to reerupt, extract if alveolar plate is compromised	Dental radiograph, observe and allow to reerupt, surgical or orthodontic repositioning, root canal treatment
Uncomplicated crown fracture	Restore tooth, smooth sharp edges, dental radiograph to rule out root fracture	Restore tooth, smooth sharp edges, radiograph to rule out root fracture
Complicated crown fracture	Dental radiograph, pulp treatment, restore or extract tooth, observe for infection	Dental radiograph, pulp treatment, restore tooth, observe for infection, may require root canal treatment
Root fracture	Dental radiograph, extract if root fracture is in middle or cervical third of root	Dental radiograph, splint, may require root canal treatment; if in cervical third, may need to extract
Avulsion	Do not replant, dental radiograph to rule out intrusion if tooth is not located	Do not handle the root, replant within 30 min or place in recommended transport medium (balanced salt solution, cold milk); dental radiograph, replant and splint as soon as possible; systemic antibiotics, soft diet, chlorhexidine, close follow-up

to facilitate the time-sensitive therapies for dental injuries.

Suggestions for Pediatricians

1. Counsel parents/caregivers about ways to reduce the risk of dental trauma through injury-prevention strategies.
2. Establish collaborative relationships with local general and pediatric dentists to facilitate referral of patients with traumatic dental injuries.
3. Understand the differences between treatment recommendations for primary and permanent tooth traumatic injuries.
4. Recognize when traumatic dental injuries require immediate treatment by a dentist.
5. Recognize when traumatic dental injuries can be initially managed by the pediatrician or primary care

physician with subsequent referral to a dentist.

The decision to initiate enteral feedings is multifaceted, involving medical, financial, cultural, and emotional considerations. Children who have developmental or acquired disabilities are at risk for having primary and secondary conditions that affect growth and nutritional well-being. This clinical report provides (1) an overview of clinical issues in children who have developmental or acquired disabilities that may prompt a need to consider nonoral feedings, (2) a systematic way to support the child and family in clinical decisions related to initiating nonoral feeding, (3) information on surgical options that the family may need to consider in that decision-making process, and (4) pediatric guidance for ongoing care after initiation of nonoral feeding intervention, including care of the gastrostomy tube and skin site. Ongoing medical and psychosocial support is needed after initiation of nonoral feedings and is best provided through the collaborative efforts of the family and a team of professionals that may include the pediatrician, dietitian, social worker, and/or therapists. *Pediatrics* 2014;134:e1745–e1762

INTRODUCTION

The decision to initiate enteral feedings is multifaceted, involving medical, financial, cultural, and emotional considerations. In 1793, John Hunter wrote of a patient who had a neurologic impairment affecting swallowing: “It becomes our duty to adopt some artificial mode of conveying food into the stomach, by which the patient may be kept alive while the disease continues.”¹ Today we speak of surgical options, medical options, and evidence-based outcomes; caregivers’ beliefs and roles; patient-appropriate individual intervention; family-centered care; and quality of life (QOL) considerations.

Faced with medical, social, and cultural considerations, the family often relies on the pediatrician for guidance in both the decision-making and the management of nonoral feedings. This article integrates cross-discipline information into a functional guide for the pediatrician. Specifically, this clinical report provides:

- an overview of clinical issues in children who have developmental or acquired disabilities that may prompt a need to consider nonoral feedings;
- a systematic way to support the child and family in clinical decisions related to initiating nonoral feeding;

- information on surgical options that the family may need to consider in that decision-making process; and
- pediatric guidance for ongoing care after initiation of nonoral feeding intervention.

BROAD CONSIDERATIONS IN THE NEED FOR NONORAL FEEDINGS

Children who have developmental disabilities or acquired disabilities are at risk for having primary and secondary conditions that affect growth and nutritional well-being. These conditions can manifest as inadequate intake of micronutrients, calories, and/or fluids. Prevalence rates vary greatly, even within diagnostic cohorts. Nonetheless, evidence from the past 2 decades supports the ability to improve nutritional outcomes among children who have neurologic disabilities (eg, cerebral palsy, Rett syndrome, trisomy 21, myelomeningocele).^{2–4}

Deficiencies in micronutrients may develop in children who have underlying metabolic disorders who are treated with medically prescribed specialized diets, such as low-protein diets in patients who have urea cycle disorders. Some caregivers may also self-prescribe special diets to their children, in attempts to organically improve the underlying developmental disability. There is no substantial evidence supporting the addition of generic micronutrients as long as the child's caloric needs are being met through a balanced diet. Restrictive diets may lead to significant nutritional deficiencies unless appropriately monitored.

Among youth who have suboptimal dietary intake, several deficiencies occur more commonly than others. For example, iron deficiency, a relatively high-risk condition for children who have feeding disorders, can affect well-being even when the iron deficiency has not yet created an actual anemia.⁵ It has been associated with sleep disorders

in children and manifestations of inattention.^{6,7} Zinc is important in neurodevelopment; its deficiency is associated with a variety of symptoms, including loss of appetite and skin problems. For patients who have chronic nutritional stressors and comorbid developmental disabilities—particularly if surgery is being planned—the status of other vitamin and micronutrient stores may need consideration.^{8,9} For children who are fed prepared formulas (oral or nonoral) as the primary source of nutrition, micronutrients are provided in sufficient amounts only if the adequate amount of formula is actually being consumed and tolerated.¹⁰

Many youth who have developmental disabilities have comorbid conditions requiring medications. The potential for reciprocal interaction exists: the influence of medication on nutritional status, and the effect of nutritional status on bioavailability and metabolism of medications. Some medications have adverse effects, such as nausea, diminished appetite, or diarrhea. Anti-epileptic drugs can be associated with secondary deficiencies of nutrients such as vitamin D and carnitine. Table 1 includes medication categories and their relationship to nutritional status. For some families, the ability to accurately administer medications orally can be problematic because of dysphagia, dystonia, other disorders of movement or coordination, or clinically significant reflux or emesis.

Among children who have neurodevelopmental disabilities, barriers to adequate oral intake can be related to underlying neurologic dysfunction. The enteric nervous system, developing primarily from the neural crest cells, is the so-called “brain of the gut.” Although it functions independently of the central nervous system (CNS), it also interacts with the CNS by prevertebral ganglia of the spinal cord and/or via the efferent action of the vagus nerve. Among chil-

dren who have underlying differences in CNS development, associated dysfunction in gut motility or gastroesophageal reflux (GER) can contribute to the challenges of ensuring adequate nutritional intake and absorption. Sometimes these problems are progressive and degenerative; it is not uncommon for children who have disorders of energy metabolism (such as mitochondrial disorders) to experience worsening gut dysmotility over time.

Vomiting or retching is relatively common among children who have developmental disabilities. The underlying cause of these can inform decisions about approaches to nonoral feeding. Vomiting attributable to GER can be addressed through a combination of positioning, food or formula selection, medications, assurance that constipation has been alleviated, and/or surgery. Retching is the first stage of the emetic reflex and is not always related to GER. Poor modulation of gastric vagal afferents can act as a potent activator of the forceful emetic reflex. Recognition of this CNS process as the etiology of emesis is important, because this process may well continue even after a fundoplication procedure and can have a negative effect on the surgery's long-term success.^{11–13} Dysmotility, mentioned previously, can also be a contributor to vomiting or retching.

Oropharyngeal incoordination, resultant poor bolus formation, and/or inadequately controlled bolus propulsion can result in subsequent airway penetration or outright aspiration. If sustained, chronic pulmonary dysfunction and/or reactive airway disease can result. These problems, in isolation or in addition to GER or gut dysmotility, may diminish the child's desire to eat orally.¹⁴

Frank aspiration identified in modified barium swallow studies invites the discussion of moving to a nonoral feeding route. However, these studies are rarely so “black and white.” Penetrations of

TABLE 1 Potential Clinical Problems in Selected Medication Use and Nutritional Status

Category	Medication (Examples)	Comment
Anticonvulsants	Valproate	Potential for carnitine, folate, copper, selenium, and/or zinc deficiency
	Phenytoin	Potential for folic acid, calcium, vitamin B ₁ , vitamin B ₁₂ , vitamin D, and/or vitamin K deficiency
	Phenobarbital	Potential for folic acid, calcium, biotin, vitamin D, and/or vitamin K deficiency
	Carbamazepines	Potential for biotin, folic acid, and/or vitamin D deficiency
	Lamotrigine	Occasional nausea and/or vomiting
	Levetiracetam	Potential for biotin, folic acid, and vitamins B ₆ and/or B ₁₂ deficiency
	Topiramate	Renal tubular acidosis and pancreatitis, renal/bladder stones
Stimulants	Methylphenidate and associated stimulants used in attention-deficit/hyperactivity disorder	Appetite suppression Slow height growth Potential for weight loss
Muscle relaxants	Diazepam and others in this class	Highly protein bound; with malnourishment and loss of serum protein there may be enhancement of drug effect Take into consideration re: pain management, respiratory depression
	Baclofen	Constipation
Corticosteroids	Dexamethasone	Increased appetite or diminished appetite; impact on taste Diminished calcium and phosphorous absorption; increased risk for gastritis
Antibiotics		Potential for diarrhea related to gut flora change; probiotic therapy shown to minimize adverse effects
Antidepressants		Reports indicate that among individuals who have major depressive disorder, there may be deficiencies in folate, vitamin B ₁₂ , iron, zinc
Anticholinergics	Oxybutynin	Constipation, dry mouth

some textures may merely require alteration of oral feeding techniques. Techniques of bolus size selection and pacing of bites, for example, may allow a somewhat tedious but acceptable method for continued oral feedings. Thus, these studies may inform decisions, but should not, in isolation, mandate surgical intervention.

Suboptimal fluid intake leads to chronic-intermittent constipation. This, in turn, can result in diminished appetite. The circular pattern of a feeding disorder, leading to diminished safe fluid intake, resulting in constipation, contributing to further feeding disincentives and

even emesis, is too common among children who have neurodevelopmental disabilities.

SPECIFIC CONSIDERATIONS: CHILDREN WHO HAVE A NEED FOR NONORAL FEEDINGS

Detailed description of the vast array of neurodevelopmental or acquired disabilities and their unique nutritional challenges is beyond the scope of this report. In particular, 2 important complex cohorts of children are not included: (1) very preterm or sick neonates being managed in a neonatal ICU,¹⁵ and (2) children receiving prolonged total

parenteral nutrition.¹⁶ Presented below are examples of common conditions associated with nutritional/feeding challenges among children who have special health care needs. Hopefully, these can guide approaches to care for the broader array of children who have special needs seen in pediatric clinical settings.

Children Who Have Cerebral Palsy

Cerebral palsy refers to a group of static brain insults affecting the development of movement and posture, often with differences in tone (diminished, increased, or mixed). The functional implications of insults occurring in early development can extend beyond motor impairments to impairments of visual-motor skills, communication, cognition, and behavior. Similarly, neuromuscular and enteric nervous system dysfunction can manifest as ongoing or worsening issues. Comorbid conditions, such as seizure disorders, hearing impairments, abnormal muscle tone, or postural instability, can be present.¹⁷ Any of these factors (or multiple combinations) can affect eating and swallowing skills, leading to nutritional compromise.¹⁸

Feeding problems for children who have cerebral palsy may manifest as oral fluid/food spillage while feeding, increased length of meals (often confused as “behavioral”), coughing/gagging with feeding, recurrent lower respiratory infections, GER, and/or nasal reflux from the posterior pharynx. These or other “red flags” suggestive of dysphagia should be considered when the child fails to grow or maintain appropriate health.^{19,20}

For decades, identifying the best method to evaluate and monitor growth and nutrition in children who have cerebral palsy has challenged pediatricians. Weight, weight-for-height, segmental measures, skinfold measures, and other techniques each have some value, but none is easily and consistently applied

with assurance of accuracy across the population of children who have cerebral palsy.^{21,22}

In the pediatric medical home, serial measures of the child's weight remain the most common practice; this offers a useful way to track trends in growth and nutrition longitudinally. Obtaining consistent measures in a clinic setting can be challenging but can be enhanced by use of a consistent scale (balanced to 0 at each visit) and by weighing the child consistently in light clothing, with a dry diaper, and without shoes, orthotic bracing, wheelchairs, or other confounders. Weights should be plotted on standard growth charts at each visit.^{23,24}

Consultation with a pediatric dietitian can be useful when there are declines in trends of weight, struggles with feeding/drinking patterns, GER, constipation, or compromised bone health. A detailed analysis of protein, fluid, calorie, or fiber intake; mealtime patterns; socioeconomic factors; and behavioral factors can facilitate approaches to optimal intake and growth. The overall energy expenditure of the child, including changing manifestations of spasticity or dystonia, deserves consideration when changing trends in weight are noted.²⁵ After the aforementioned factors have been addressed in an effort to support successful oral feeding, if the child remains unable to safely and effectively meet his or her nutritional requirements orally, options for adjunctive nonoral feedings should be considered.

Children Who Have Myelomeningocele

A common feature among children who have myelomeningocele is the presence of a Chiari II malformation, which can be associated with central apnea and/or dysphagia. In infants, the "suck, swallow, breathe" rhythm can be disrupted. Excessive gag reflex can be confused

with GER. Children who have vocal cord dysfunction related to the Chiari II malformation may require tracheotomy; not uncommonly, nonoral feeding via gastrostomy tube is recommended for pulmonary safety.

Development of the enteric nervous system takes place as neural crest-derived cells migrate and differentiate.²⁶ Dysmotility in children who have spina bifida, related to alterations in the enteric nervous system and altered parasympathetic innervations, can manifest from the esophagus downward throughout the intestinal tract. Modified barium swallow studies performed carefully to replicate *actual* feeding circumstances can be greatly helpful in symptomatic children. If alteration of textures and changes in feeding techniques fail to support adequate nutrition and/or safe oral feedings, options including nonoral feedings must be discussed. As children grow into early elementary school age, the anatomy of the head, oropharynx, and neck shift in relative proportions. A repeat modified barium study may be warranted to define new parameters of safe feeding.

Among children who have thoracolumbar-level myelomeningocele who demonstrate severe kyphoscoliosis, peculiar chest/abdomen anatomy, or both, feeding problems can occur related to posture, positioning, underlying internal anatomy, and GER. These, in concert with dysphagia related to the Chiari II malformation, create complex feeding challenges.

Adequate nutrition is critical to maintenance of skin integrity. Too often, the combination of insensate skin, moist skin, and exposure to local tissue injury results in significant wounds among children who have myelomeningocele. Successful management of serious wounds demands higher intake of protein, calories, and micronutrients.²⁷ Children who are marginally able to

meet their fluid and nutritional needs orally may need adjunctive feedings for relatively short duration (8 weeks or less) to promote wound healing; others may require nonoral feeds for longer periods.

Children Who Have Cleft Conditions and/or Micrognathia

Micrognathia (mandibular hypoplasia) has its origin in the first trimester of intrauterine development. The abnormally high position of the tongue can result in a cleft of the soft palate. A severe form of this process results in the Robin sequence. The recessed jaw and tongue are often associated with low tone and weakness of facial musculature, increasing the risks for airway obstruction and aspiration of oral feedings.²⁰ For infants affected by these conditions, nasogastric tube feeding or gastrostomy tube feeding may be required from birth for months at a minimum.²⁸ Reid and colleagues provide an excellent review of feeding issues relative to cleft lip, cleft palate, Pierre-Robin sequence, and other cleft conditions. Their longitudinal studies spotlight the conditions for which adjunctive nonoral feeding measures might be indicated.²⁹

Children Who Have Neurodevelopmental Disabilities

GER is a common finding among children who have neurodevelopmental disabilities.³⁰ The reflux can be related to a spectrum of underlying and sometimes uncommon conditions, including anatomic conditions, such as hiatal hernias or structural anomalies. *Helicobacter pylori* gastritis as a cause remains a point of debate.^{31,32} Celiac disease can be a comorbid condition in various genetic syndromes.^{33,34} Behavioral characteristics, related to underlying pain or temperament differences, can be confused with GER. Eosinophilic esophagitis should be considered in the differential diagnosis, especially in

children not responding to appropriate reflux management.³⁵

It is important to also consider a primary underlying central nervous system injury in the differential. For example, a group of infants who had either perinatal injury or dysphagia without specific etiology were found to have high-intensity lesions in the lower pons and medulla and pontomedullary atrophy on MRI studies. This suggests that a vagovagal reflex, mediated by brainstem function, might contribute to the disturbed motility of the upper digestive tract in some children.¹³

Children who have genetic syndromes and other developmental disabilities often require elective surgeries for a variety of reasons, such as scoliosis, contractures, and hip dysplasia. Because of the hardware inserted, casts applied, or the required postsurgical positioning, their previous unique posture for feeding may be compromised. If this “natural posturing” previously served as compensation for occasional aspiration or as assistance in moving and swallowing a bolus of food or fluid, then the potential for postoperative pulmonary events can be increased. Preoperative planning by the surgeon, the pediatrician, the pediatric hospitalist, the family, speech or occupational therapists, and the dietitian allows for presurgical intervention to minimize such risks. Table 2 outlines some presurgical considerations.³⁶ On the basis of a holistic assessment, consideration of nonoral feeding for a period before surgery (for optimal nutritional stores and pulmonary status) and for a period postsurgery (for wound healing and airway safety) may be necessary.

Children in Palliative Care

Elements of ethical decision-making are recurring considerations in the daily and year-to-year care of children who have developmental or acquired

disabilities. Often, decisions are made without deliberate attention to conversations about prognostic or ethical implications. The Association for Children’s Palliative Care published a *Guide to the Development of Palliative Care Services*, which includes information about children who have developmental disabilities.³⁷ Some children receiving palliative care coordination may be in an imminent terminal-care stage; for others, the trajectory of deterioration may be months or longer. Because such prognostication can be difficult, special consideration and flexible planning for nutritional support is required.

In some circumstances, families and members of their support system may decide against further nonoral nutrition/hydration interventions.³⁷ Otherwise, nutritional support care plans should be devised (1) after identification of likelihood of risk for malnutrition (energy needs, nutrient needs, effects of medications, effects of underlying condition), (2) in concert with family, physicians, palliative care team, pediatric dietitians, and the speech pathologist monitoring oral-motor skills, (3) whenever

safe and possible, to allow continued oral nutrition (with preferences of the child considered), and (4) to maintain energy, minimize pain or irritability, and focus on overall (not just health-related) QOL goals. These care plans may vary over time because of activity, mobility, tone issues, fever fluctuations, skin integrity, or acute illnesses.

The terminal nature of conditions warranting palliative care intervention places a spotlight on many decisions relative to care and support. Decisions related to nonoral feedings—adjunctively or solely—require sensitive awareness of individual needs. To greater or lesser degrees, similar shared decision-making is needed for any child being considered for nonoral feedings.

SHARED DECISION-MAKING: A MULTIFACTORIAL PROCESS

Ultimately the concerns outlined previously are helpful signposts, but no single clinical finding in isolation is an absolute indication to avoid *all* oral intake and move solely to nonoral feedings indefinitely. Rather, the multiple components serve as discussion

TABLE 2 Considerations Before Surgical Procedures: Nutrition, Airway Safety, and Surgery: Considerations for Nonoral Feeding Intervention

Developmental disability with known dysphagia, airway concerns
Significantly underweight/failure to thrive
Pulmonary function and reactive airway disease: status and optimal management
Suboptimal nutrient status (calories/vitamins/micronutrients/protein/iron/other)
Medication–nutrient interaction
Cultural requirements for special or specific diets
Financial/insurance issues related to pre- or postoperative nutrition support
Formulas
Equipment
Nursing or personal care assistance
Postoperative supplements likely to be needed
Potential need for total parenteral nutrition
Peripheral venous access versus central
Energy needs
Baseline
Anticipated NPO status for planned procedure
Wound-healing support
Likelihood of repeat operating room procedures requiring NPO status
Oromotor feeding
Iatrogenic factors likely to impact feeding abilities
Postoperative pain management plan and nutritional considerations
NPO, no oral intake.

points for collaboration among the patient, the family, and the health care professionals.

Considering both the clinical status and the social contexts of the child, questions to be considered include:

- Do they support adequate caloric, nutrient, and fluid intake?
- Do they support optimal health-related quality of life (HRQOL)?
- Do they support optimal QOL?
- Are the present conditions optimal? Safe? Psychosocially and clinically sustainable?
- Do they allow a combination of oral and nonoral intake?
- Is the present situation temporary, or is it likely to be ongoing or progressive?
- Are potential changes in feeding methods and schedules *realistic* for the family?

An informed and sensitive approach is in order. This is best accomplished using a cross-discipline approach. After discussion with the patient and the family, these decisions can be direct and straightforward, exceedingly difficult, or somewhere along that spectrum.^{38,39}

Although families and professionals each use the term “quality of life,” this can be projected and/or perceived variably. Neither clinicians nor researchers have yet to agree on a universal definition of either QOL or HRQOL. For purposes of this article, the following are general descriptions:

- QOL: the overall sense of well-being, including aspects of happiness and satisfaction with life as a whole
- HRQOL: aspects of QOL that affect health (physical or mental) or are affected by health and that are associated with life satisfaction^{17,24}

Petersen et al described caregivers’ perceptions of nonoral feeding for children who have developmental disabilities.

Most of these perceptions were encapsulated in either the QOL or the HRQOL categories (suggested even in the article’s title, “Eating and Feeding are Not the Same”).⁴⁰ The complexities and contradictions in “coming to consensus” on this topic were nicely outlined with several concerns generated from families:

- Is the enteral feeding a confirmation of the permanence of the child’s disability?
- Will it increase discrimination and be viewed as additional stigma?
- Will it produce a loss of the nurturing, parental experience for the caregiver?
- Will it prevent “pleasure of eating” for the child?
- Will it prevent mealtime social associations?

Mahant et al⁴¹ conducted a qualitative systematic review of publications focused on the experiences of parents who had actively participated in the decision-making before initiation of nonoral feeding for their children who had neurologic disorders. The authors identified 3 major themes related to decision-making:

- Context: characteristics unique to the family, child, and the circumstances bearing on each
- Values: attitudes, beliefs, and belief systems affecting decisions regarding nonoral feedings for nutritional support
- Process: the perceived manner of decision-making in concert with health teams

Figure 1 offers a schematic of example factors contributing to *decisional conflict* or *decisional resolution* based on a modification of Mahant’s work. The outline supports the concept of shared decision-making to minimize conflict and enhance decisional resolution. For the pediatrician involved in

this process, Shakespeare’s words are a useful reminder: “The web of our life is of a mingled yarn, good and ill together.”⁴² How the terms “good” and “ill,” “quality of life,” “medically necessary,” “comfort,” and others are defined is unique to the family, the child, and the clinical situation. Unmingling the yarn requires time, sensitivity to the situation, and a knowledge base to provide information, support, and collaboration.

Beyond the emotional, social, cultural, or financial aspects of nonoral feedings, other clinical considerations include:

- Growth differences: growth failure, diminished growth trajectories
- Malnourishment⁴³
- Dysphagia and associated respiratory complications
- Skeletal problems or other comorbid conditions with links to nutritional concerns
- Neurologic conditions directly affecting gut motility and fecal evacuation
- Comfort, sleep, and behavioral issues manifesting in a poorly nourished child

Medical conditions resulting from or contributing to suboptimal growth and nutritional health should be assessed before recommending nonoral feedings. Table 3 lists laboratory and/or clinical evaluations that might be useful.

Once consensus is reached to go forward with adjunctive feedings for nutritional support, more options await the family and support team. Figure 2 offers a decision-tree approach to the information that follows.

When oral feeding is deemed insufficient for adequate nutrition, an early consideration is: “How long is the nonoral feeding regimen likely to be needed?” If the estimate is a relatively short period (<8 weeks), use of

**FIGURE 1**

Nonoral feeding and shared decision-making: resolution versus unresolved conflict (modified from Mahant⁴¹).

a nasogastric (NG) tube feeding regimen might be considered. If there is clinically significant preexisting GER, the alternative use of a nasojejunal (NJ) feeding tube may be advantageous. On the basis of the child’s primary and comorbid conditions, these tube feedings may be variably tolerated. Thus, families will need education on reinsertion of NG tubes; NJ replacement typically requires fluoroscopic guidance. The goal is resumption of oral feeding once the acute situation has resolved.

If adjunctive or total nonoral feedings are likely to be longer in duration,

consideration of a gastrostomy button (or tube) should be considered. This is particularly appropriate for the child who is engaged in a “typical” environmental schedule (eg, school, community, sports). For children who have ongoing need for nonoral feedings, the gastrostomy tube is better tolerated physically, socially, and functionally than NG or NJ tubes. Several types of approaches and equipment are available as options: (1) a percutaneous and endoscopic procedure for gastrostomy button insertion, (2) a surgically placed button (or tube) into the stomach, or (3) gastrojejunal tube insertion.

Advantages and constraints of the various methods of nutritional delivery should be a part of the shared decision-making process. For example, the family can “bolus” feedings (deliver an adequate-volume “meal” in a relatively short timeframe) via the NG tube or the gastrostomy button when GER or excessively delayed stomach emptying are not serious concerns. Alternatively, extended-time feedings are necessary when jejunal feedings are required.

Before placement of a gastric button in a child who has neurodevelopmental disorders, there should be

TABLE 3 Clinical Laboratory Tests and Other Clinical Studies That May be Useful Before Nonoral Feeding^a

Clinical Investigation	Specific Measures
Serum	Iron panel and serum ferritin Zinc; 25-OH vitamin D Protein/albumin Celiac panel Complete blood cell count and metabolic panel
Urine	Urine analysis
Imaging	Upper gastrointestinal tract study to rule out malrotation, other anomalies If clinically indicated, nuclear medicine gastric emptying study
Biopsy/scope	Eosinophilic esophagitis Celiac disease, gastritis

^a Investigations listed are meant as a guide for thoughtful consideration, not a standard of practice.

consideration of signs or symptoms of delayed gastric emptying. If emptying is somewhat slow, this can be improved through altering formula selection, volumes per feeding, schedule of feedings, or rate of feedings and with medications such as erythromycin or metoclopramide. If the emptying time is

significantly delayed and these considerations are not accounted for, the child remains at risk for emesis, discomfort, and potential aspiration.⁴⁴

Excluding decisions for nonoral feedings that are precipitated by acute severe medical/surgical/traumatic emergencies, the ultimate decision to move forward

with nonoral feedings can best be supported if the family has had a preceding and continuing relationship with a pediatric dietitian. Nutritional guidance and information sharing is central to the care of the child who has developmental or acquired disabilities; thus, the dietitian should be included in the core decision-making team. Micronutrient composition of formulas and the caloric requirements of the individual child vary; they require close monitoring and direction.^{45,46} Nutritional assessments periodically allow for earlier identification of the at-risk child. Having a preexisting understanding of the family's concerns and values provides greater credibility when more difficult conversations and decision-making are required.⁴⁷ A strong alliance between the pediatrician, the speech therapist, and pediatric dietitian—whether within the pediatric office or at a location for ready

**FIGURE 2**

Decisions in adjunctive feedings of the child/adolescent with developmental disabilities.

referral—best serves the families of children who have disabilities.

OUTCOMES STUDIES THAT INFORM DECISION-MAKERS

As families consider (1) surgical placement of a gastrostomy button as an adjunct to or for replacement of oral feedings, and (2) the advisability of a gastric fundoplication for comorbid GER, the need for best evidence of optimal outcomes arises. Studies of children and families have been published describing outcomes of gastrostomy tube placement and feeding. Although limited in scope and number, the outcomes provide the pediatrician and the families with some data for decision-making (Table 4). Extant literature suggests that if the decision points outlined previously are addressed and the medical needs are identified, the pediatrician can assure parents and children that the nonoral feeding option can be positive. This can be stated in regard to both physical *and* QOL considerations. Variances in adverse events point to the “operator-dependent” nature of the surgical procedures, to pre-existing comorbidities, and to supportive aftercare.

The psychosocial and emotional considerations in qualitative outcome studies emphasize the value of physician-to-parent and parent-to-parent support in decision-making regarding nonoral feeding. Conversations about what constitutes “normal” can help to alleviate an overwhelming sense of disappointment or guilt in going forward. “Normal nutrition” involves adequate fluid intake, adequate caloric and nutrient intake, achieving a sense of satiety, achieving typical growth patterns, safety in delivery of food (eg, avoidance of aspiration), and good health. Often these components are compromised in oral feeding of children who have disabilities but are improved with adjunctive and/or replacement nonoral feedings.

Support for the child and family should begin well before decision-making and placement of the gastrostomy tube. Protocols for educating and instructing families about the gastrostomy tube can inform the clinical decision process. Such protocols can include hands-on feeling of the devices, doll models for adults and children alike to better understand anatomy, drawings, and verbal reinforcement. This information is valuable early in decision-making, but reinforcement is needed in the months and years thereafter as the child grows and new situations require updating of feeding regimens.

Fundoplication Surgery

The need for antireflux intervention is a common topic as families consider gastrostomy tube placement. When pharmacologic and/or dietary interventions have been exhausted, a common surgical option is the Nissen fundoplication (or a modification). The goals of fundoplication include (1) restore the intra-abdominal esophagus, (2) restore the angle of His, (3) reconstruct the diaphragmatic hiatus (when necessary), and (4) reinforce the lower esophageal sphincter and increase basal lower esophageal sphincter pressure.⁴⁸

The value of fundoplication surgery with or without gastrostomy tube placement has, for decades, been a focus of debate and contradiction. To some degree, it remains so even now. When GER is highly suspected clinically before gastrostomy tube placement, evaluation by nuclear medicine, direct endoscopic visualization/biopsy, classic pH, or multichannel intraluminal impedance-pH studies are options for assessment.⁴⁹ Despite the advancement of technical methods of measuring esophageal parameters, ongoing lack of clarity remains as to the clinical relevance of the measurements and their predictive value after surgery.^{44,50-52}

Again, evidence-based outcome studies—limited as they are—provide an element of understanding when advising families. Unlike the studies on gastrostomy tube placement outcome, the data from studies related to fundoplication surgery fail to suggest which patients might be best suited for the procedure. For example, a study of reflux using multichannel intraluminal impedance-pH studies provides insight into the technical challenges in administering the examination, although the patients described excluded children who have overt neurologic disorders, metabolic disorders, or respiratory and/or gastrointestinal malformations.⁵³ In response to earlier suggestions for “the need for a ‘protective’ antireflux operation in children referred for feeding gastrostomy,”⁵⁴ Puntis et al provided data “in the child with neurological disabilities without symptoms indicating severe gastroesophageal reflux” and their conclusions that “fundoplication is unlikely to be necessary as a consequence of percutaneous endoscopic gastrostomy” and that the number of antireflux surgical procedures should be reduced.⁵⁵ Similarly, the outcome reports of variations in fundoplication techniques (eg, open, laparoscopic) offer differences in respective advantages and disadvantages.^{56,57}

A number of complications and adverse effects have been described and attributed to fundoplication surgery: alterations in gastric tone (perhaps related to injury of the vagal nerve at operation); *accelerated* gastric emptying (“dumping syndrome”); *delayed* gastric emptying after surgery related to vagal nerve injury; and retching (potentially related to visceral afferent sensitivity and vagal nerve injury). The gas bloating syndrome (inability to belch and vomit, abdominal pain after eating, and/or dysphagia) can result from 1 or more of these complications.

TABLE 4 Summary of Recent Outcome Studies Related to Gastrostomy and Nonoral Feeding

Reference	Subject	Comments
Craig et al, 2006 ⁸⁵	Medical, surgical, and health outcomes of gastrostomy feeding	Prospective study; before and after gastrostomy; 76 children with neurodevelopmental disabilities and families. Two thirds of those with severe weight issues before achieved mean weight-for-age ($P = .001$). Other health gains included reduction in drooling, decreased secretions, less vomiting, improved constipation. Thirteen children after surgery had a significant complication (eg, internal fistula, adhesions, bleeding).
Enrione et al, 2005 ⁸⁶	Medical and psychological experiences of family caregivers with children fed nonorally	Qualitative study addressing the caregivers of children with gastrostomy tube feedings and whether they had problems and/or concerns themselves. Questionnaires sent to 150 families (37 participated). Major psychosocial issues included: "I feel sad because my child is deprived of many social activities that involve eating"; "I feel depressed about not being able to feed my child by mouth," "In my absence, I have trouble finding (someone to) feed my child." Over the course of the year after surgery, the medical concerns became less and the ranking of psychosocial issues increased.
Mahant et al, 2009 ⁸⁷	Tube feeding and quality of life in children who have severe neurologic impairment	In general, caregivers reported a positive effect on the child's health, particularly with regard to feeding, administration of medications, and weight gain. Based on use of nonvalidated questionnaire that used visual analog scale. Procedure deemed "safe" and with "few major complications" by parent reports.
Martinez-Costa et al, 2011 ⁸⁸	Early decision of gastrostomy in children who have severe developmental disability	Structured telephone script allowed input from parents of 26 children with severe disabilities. Caregivers "showed high satisfaction (91%)" and 87% noted they would have decided earlier to go forward with gastrostomy "had they anticipated the outcome." Patient management and family dynamics (including the child) were noted to have "improved considerably."
Samson-Fang et al, 2003 ⁸⁹	Effects of gastrostomy in children who have cerebral palsy using the AACPDM method for evidence reports	This important review considered previous outcome studies from 1956 through 2002, offering historical perspective in addition to detailed descriptions of studies and outcomes. Generally, the report cited less than robust levels of evidence and the need for further well-designed studies. There was a general consensus (low levels of evidence) of gastrostomy placement being "helpful."
Sleigh and Brocklehurst, 2004 ⁹⁰	Effects of gastrostomy feeding in cerebral palsy: another systematic review	This evidence-based review from the United Kingdom resulted in findings similar to those of Samson-Fang in 2003 and encouraged further studies with higher levels of evidence.
Sullivan et al, 2004 ⁹¹	Impact of gastrostomy feeding on the quality of life of caregivers to children who have cerebral palsy	Although the purpose of gastrostomy placement is solely for the care and benefit of the child, the parents continue to act as the "partners in feeding." Caregivers of 57 children with cerebral palsy reported significant reduction in feeding times, increased ease of drug delivery, and reduced concern about their child's nutritional status. In concert with these findings, the caregivers reported (12 mo after gastrostomy placement), that they, themselves, had significant improvement in social functioning, mental health, energy/vitality, and general health perception.
Wilken, 2012 ⁹²	A qualitative meta-analysis of maternal emotional state after initiating tube feeding in their child	A review of 7 qualitative studies (1997–2007). Both oral and tube feeding have multiple meanings for parents and "signify more than obtaining an adequate nutritional intake." Decisions about gastrostomy tube placement are complex and often difficult. A significant percentage of mothers noted lack of support during the decision-making process. After the tube insertion, there was description of both relief and disappointment (in "giving in" to the nonoral feeding).

The onset of postsurgical dumping syndrome (which can be observed irrespective of presurgical gastric emptying time studies) has been reported.^{48,58} Treatment of this condition can be approached by use of thickeners, selective formulas, nutritional supplements to formula being used, and pureed feedings in addition to or rather than formula only.^{59–61} If dumping syndrome is suspected and/or sustained, consultation with a gastroenterologist for formal diagnosis and collaborative treatment plans should be considered. Thus, on the broad question of “Is my child a good candidate for fundoplication?” recent clinical studies and reviews leave physicians and families very much where they have been for decades: fundoplication for the control of GER in children needs further evaluation.^{62,63} Given the lack of strong data from outcome studies with high levels of evidence, the decision for or against fundoplication at the time of gastrostomy tube placement remains a highly individual judgment. The severity of the reflux and its effects on the child, the response to previous vigorous medical treatment of GER, the outcome experiences of and opinion of the pediatric surgeon (relative to fundoplication procedures), and comorbid medical/developmental conditions (ie, tracheotomy) are examples of components in the decision-making process. Qualitative studies and those focusing on HRQOL generally reflect a positive experience for the child and family after fundoplication.^{64–66}

POSTOPERATIVE SUPPORT AND COLLABORATIVE CARE

Although the choice for surgery can be considered a “landmark” decision, ongoing medical and psychosocial support is needed for an extended period after the procedure. This follow-up is best provided in the context of a collaborative commitment involving family,

pediatrician, and colleagues, such as the dietitian, speech pathologist/occupational therapist, and social worker. Collaborative care is outlined in 3 categories: (1) the roles of professionals and caregivers, (2) care of the gastrostomy tube and skin site, and (3) coordination of oral and nonoral feeding goals.

Roles of Pediatrician, Pediatric Dietitian, and Caregivers

For families, the process of surgery, equipment procurement, formula prescriptions and delivery, and ongoing care can become fragmented and problematic. Gordon et al described the value (emotional, financial, and medical) of a closely interconnected partnership between the tertiary care providers (such as developmental pediatric dysphagia teams) and the primary care physician for medically complex and fragile children who have special health care needs. Particularly valued by families was having a single “point professional” (eg, nurse, coordinator) at the primary care office and at the tertiary care center as their portals of entry; likewise, having those 2 resources in communication was deemed important.⁶⁷

On some periodic basis, specific inquiry of the family as to how the feedings are going provides an opportunity to acknowledge the long-term decision and to gather answers to specific questions/concerns about the process: effect on siblings; time and scheduling of feedings if different from other family members; need for advocacy relative to agencies, schools, child care facilities, or other; description of typical day and night schedule; most difficult aspect of the nonoral feeding at particular times (if any); level of perceived well-being by the primary caregiver(s); and any effects (positive or negative) on the child's social activity and participation.^{68–70}

Medical considerations for the long-term include monitoring for multiple

associated conditions in many ways similar to those focused on before surgery^{10,71,72}:

- Undernutrition, overweight, micronutrient deficiencies, food allergy-associated eosinophilic esophagitis
- Dental (gum and teeth) health status
- Medication changes from other subspecialists (eg, seizure medications)
- Pulmonary status and sleep status and their potential relationships to feedings
- Changing body structure (eg, scoliosis, osteopenia)
- Changing body function (eg, strength, tone, gut motility, oral motor dysfunction)
- Skin health, particularly around the gastrostomy tube site

The Pacific West Maternal & Child Health Distance Learning Network – CSHCN Nutrition (http://depts.washington.edu/chdd/ucedd/ctu_5/pacwestcshcn_5.html) offers a series of modules on nutrition for children who have special needs that are clinically relevant and supportive to the primary pediatrician.

The Academy of Nutrition and Dietetics has created “Standards of Practice and Standards of Professional Performance for Register Dietitians (Competent, Proficient, and Expert) in Intellectual and Developmental Disabilities.” Dietitians who have met criteria for “proficient” or “expert” in this field can be a remarkable resource to families and physicians alike when addressing ongoing clinical issues of nonoral feedings: construction of long-term nutrition plan; integration of feeding into home, skilled nursing, or school settings; updating feeding needs; problem solving (mealtime supports, technical feeding issues, communication skills of the child, changing levels of interdependence); advocacy with supporting agencies; and monitoring of nutritional status over time.^{23,36,73} See example forms

in Figs 3 and 4 for use in supporting families.

Care of Gastrostomy/Gastrojejunal Tube

Even if the care of the gastrostomy tube and associated conditions are managed mostly through the tertiary care center, the family is well served by the primary medical home that is familiar with care and maintenance of the gastrostomy button. For the pediatrician, helpful resources include:

- http://www.vygon.co.uk/pdf/upload/Enteral_Feedingfull.pdf
- <http://emedicine.medscape.com/article/149589-overview>
- <http://www.slideshare.net/jessicalynn-smith/finalpresentation-13485393>

These tutorials provide information on types of feeding tubes, stoma site care, tube maintenance, tube removal and replacement, and tips for problem solving. Beginning in 2014, a global initiative began to institute a unified set of industry standards for safer connectors that ensure compatibility and reduce the likelihood of tubing misconnections in enteral feeding systems.

Differences remain among pediatricians and surgeons as to their personal preferences for gastrostomy button replacement: some set a particular calendar schedule; others suggest a change only when the current button is faltering. Regardless, families should have available at all times either a spare button or Foley catheter (same diameter size as button) for unexpected loss of the gastrostomy button. If an emergency department or medical office is not immediately available, the family should know how to replace 1 of these until they can be seen by a medical professional.

Incorrect medication delivery through the tube can result in clogged tubes, decreased drug delivery, and/or drug-formula incompatibilities (particularly

common: phenytoin, carbamazepine, fluoroquinolones, and proton pump inhibitors). Most medications should not be added into the enteral formula bag. Medications need to have the tubing line flushed with warm water before and after dosing. If in question, consultation with a pharmacist will inform as to which medications can be crushed and used in which vehicle liquids.^{74,75}

Many times, the “venting tube” (or “burping tube”) that accompanies the replacement gastrostomy button kit is a highly valuable tool. For children who air-swallow and whose gastric air collection is interfering with feeding (bloating, distention, discomfort), use of the venting tube before and after feeding can ease these symptoms considerably.

Generally, the stoma site should be washed and cleansed as is the remainder of the chest and abdomen: washed with a pH-balanced bath soap, then left uncovered for access to open air. For the occasions when the site allows leakage, an absorptive wound care foam dressing will “wick” the moisture away from the skin more efficiently than cotton gauze pads.

The development of overgranulation tissue at the stoma site is not uncommon. The specific etiology of its development is not known, but several contributing factors have been suggested: reaction to a foreign body, undue pressure, repeated “trauma” or friction to the area, or excessive moisture to the area. An excellent literature review and subsequent care pathway to evaluate and manage overgranulation was provided by Warriner and Spruce⁷⁶; suggestions included:

- Silver nitrate applications have historically been used, but care must be taken to avoid damage to the tube, damage and pain to surrounding skin, and potential for further tissue damage or secondary infec-

tion at the site of the granulation tissue.

- Topical use of low-dose steroids has been evaluated; a specific tape (Haelen tape) impregnated with an appropriate steroidal preparation has been shown to be effective.^{77,78}
- If persistent, therapies used in wound care centers can be applied.
- If aggressive topical therapies are not eliminating the tissue and it is considered to be a problem (eg, bleeding, drainage onto clothing, odor, aesthetic), removal and replacement of the button/tube can sometimes help.

In the child whose dysmotility or reflux symptoms are being managed by use of a gastrojejunal tube rather than by gastrostomy and fundoplication procedure, its replacement generally requires fluoroscopy with the assistance of interventional radiologists. Migration of the gastrojejunal tube's tip from the intestine back into the stomach can result in regurgitation and aspiration. If suspected, feedings should be halted; consultation with the physician is warranted. Radiographic evaluation and tube replacement may be indicated.⁷⁹

Given the relatively small apertures in the jejunal tip of the tube, consideration of medications being delivered and formula additives being used is needed to avoid occlusion of the distal tip. It is often best to use the gastric port for medications. Clinical reports of bloating, cramping, and/or significant changes in fecal consistency warrant a review with the dietitian about volumes, rates, and osmolality of the formula being used.

Coordination of Oral and Nonoral Feeding Goals

For some, nonoral feedings are designed to be adjunctive to ongoing oral feedings. Depending on the medical circumstances that resulted in the

RE: Patient's Name
 DOB: 1/1/1111

To Whom It May Concern:

The Pediatric Developmental Disabilities team at Texas Scottish Rite Hospital for Children follows *Patient's Name*. Her diagnoses include *specific syndrome*, severe scoliosis, pectus excavatum with surgical repair x2, multiple cardiac issues, gastroesophageal reflux, asthma, and multiple pneumonias. She underwent gastrostomy placement on Jan 1, 2005, so that she may receive nonoral feedings to help her gain weight and improve her nutritional status in preparation for her upcoming scoliosis surgery.

Her most recent anthropometrics obtained on 1/16/14 were 150 cm (20th percentile/age) and 21.9 kg (<5th percentile/age). Her calculated BMI is 9.7, which is significantly below the 5th percentile for age.

Patient's Name needs a 1.5 kcal/cc formula to provide maximum calorie intake in minimal volume in addition to her oral feedings. Resource Just for Kids 1.5 w/fiber has been well tolerated by the patient. Three boxes daily will provide *Patient's Name* 1065 kcal/day (49/kg) to meet approximately 67% of her calorie needs.

Since *Patient's Name* is an active child with multiple activities and requires medical appointments, we are requesting an *XYZ Feeding Pump*. The following reasons outline why this is a unique and clinically necessary for our patient:

- 1.) **Accuracy:** The XYZ performs with a +/-5% accuracy with all solutions, across the full flow rate range.
- 2.) **Rate and dose selectivity:** The XYZ is the only enteral pump that can deliver nutrition solutions at rates as low as 0.1 mL/hour and as high as 600 mL/hour. It is also the only pump with programmable doses as low as 0.1 mL and as high as 3000 mL. *Programming flexibility allows for adjustments to the patient's therapy as needed.*
- 3.) **Battery life:** The XYZ twenty-four hour battery life capacity far exceeds any other pump. It is the only pump with a Lithium battery. A lightweight battery with long life *improves adherence with the needed feeding schedule.*
- 4.) **Portability:** The XYZ pump and disposable sets allow successful placement in custom packs or tote bags, at the bedside, on strollers, or on wheelchairs. The XYZ weighs less than 1 pound (about the weight of a can of soup) and has, by far, the smallest sized carrying pack options for pediatric and adult patients. In addition, the XYZ was designed to operate in any orientation. Many pumps require the use of a drip chamber in their disposable sets. This means they can only operate in the upright position. Patients rarely operate in an upright position. This combination of features enables health-improving physical activity.
- 5.) **Occlusion safety:** The XYZ is the only pump with upstream and downstream occlusion sensors to identify back pressure from the gut and clogged tubing. The downstream occlusion sensor is designed to alarm at a lower setting than any other pumps, specifically for the protection of pediatric patients.
- 6.) **Air alarm safety:** The XYZ is the only pump with an air detector, which detects air in the line. This protects sensitive patients from the infusion of air, which can lead to painful distention of the stomach or intestines.
- 7.) **Disposable set safety:** The XYZ disposable sets are entirely DEHP free and contain an in-line occluder, which will not allow solution to free flow into the patient if it is not loaded properly into the pump.
- 8.) **Cost savings:** The XYZ is a rugged pump designed for day-to-day handling. New sensing technology has allowed the pump to be completely sealed so it is the only pump washable under running water. In addition, it does not require annual maintenance/calibration.
- 9.) **Physical, social, and psychological benefits:** Based upon its unique feature set, the quality of life of the patient, the family, and caregiver are greatly improved by using the XYZ. The portability and ease of use features of the XYZ remove significant barriers to health-improving physical activity, allowing adults to return to work, and social interaction of patients with friends and family.

We are requesting insurance funding for the following:

- (1) XYZ ambulatory feeding pump
- (2) IV pole
- (3) XYZ 500-mL feeding bags, 30/month
- (4) Formula type 1.5 w/fiber, 750 ml (3 boxes) daily
- (5) Farrell valve gastric relief bags, 30/month
- (6) Brand g-button replacement, 2/year
- (7) Brand extension sets, 4/month
- (8) 60-mL syringes, 5/month
- (9) 10-mL syringes, 5/month

Your assistance to the family will be greatly appreciated. If further details are required, please do not hesitate to contact the dietitian at (555) 555-5555.

Sincerely,

Richard C. Adams, MD, FAAP

Wendy Wittenbrook, MA, RD, CSP, LD

FIGURE 4

Sample letter: orders for school.

need for nonoral feedings, some children will be able to later resume full oral feedings and ultimately remove the gastrostomy button. For these children,

the gastrostomy button is placed with plans for its eventual removal. For many children who have complex neurodevelopmental disabilities, the

likelihood of the gastrostomy use (solely or in combination with some oral intake) for extended times is high. To the extent that oral-motor coordination skills allow,

oral feeding can assist in dental health, maintenance of feeding skills, enjoyment, and social considerations.

Video-fluoroscopy feeding studies (modified barium swallows) are helpful in discriminating between “safe” foods and textures that can be maintained by mouth and “unsafe” textures and foods that place the child at risk for acute or chronic pulmonary conditions. By removing the “high risk” foods, the child can become less defensive (protective) of materials entering the mouth and, thereby, increase the ease and comfort of oral feeding. Repetitive fluoroscopy studies, too often based on arbitrary periodicity schedules, should not be considered a clinical requirement. The radiation exposure from an individual study is acceptable, but frequent or repeated exposures are concerning and should be guided by clinical risk/benefit considerations. Fiber optic endoscopic evaluation of swallowing offers direct visualization of anatomic pharyngeal structures during swallowing, but does not provide information about the oral phase of dysphagia or predict long-term feeding status in children.⁸⁰

Programs focused on establishing “normal” eating behaviors in children can be successful. However, it is important to understand the nature of the programs, their goals and methods, and subject selection (feeding issues among the children treated).^{81–83} For example, in 1 university-based program, the eligible children met specific criteria: resolution or stability of the medical problem causing the need for fundoplication; absence of anatomic or functional impairment precluding safe oral feeding; absence of oral-motor apraxia; maintenance of adequate weight on gastrostomy tube feedings; and/or cognitive/developmental status adequate to allow a response to behavioral therapy sessions.⁸⁴

When transition back to full oral feedings is being considered, several

questions can help guide the discussion:

- Is the child presently showing adequate growth trends?
- Have oral skills and swallow coordination and safety been recently assessed, preferably by an interdisciplinary dysphagia team?
- Has the medical condition that precipitated the need for the nonoral feeding been corrected or significantly improved?
- Are adequate professional resources (eg, speech therapist with background in feeding children who have disabilities, supports within the school setting, home supports) available to the family in the transition process?
- Are significant child behavioral issues present that could disrupt a transition plan? As the child grows and social constraints of feeding are recognized, psychosupportive therapy may be helpful in this phase of his or her “adjustment to disabilities.” New strategies for coping and interacting with peers and with others in the community may require focused cognitive behavioral therapeutic approaches, especially if the likelihood of nonoral feeding is ongoing.

CONCLUSIONS

The decision to begin nonoral feedings for a child who has acquired or developmental disabilities is complex. Aspects of medical care, cultural values and beliefs (of both the family and the health care professionals), and emotional investments deserve consideration. A commitment to surgery and nonoral feedings involves active dedication by the family, physicians, caregivers, dietitians, social workers, and others involved with the child’s care. This commitment is needed in the process of coming to a decision,

taking action on the decision, and especially after a surgical procedure. Optimal function, health, quality of life, safety, comfort, and care should be underlying components driving collaborative plans and support of the child.

FREE

The passage of the Best Pharmaceuticals for Children Act and the Pediatric Research Equity Act has collectively resulted in an improvement in rational prescribing for children, including more than 500 labeling changes. However, off-label drug use remains an important public health issue for infants, children, and adolescents, because an overwhelming number of drugs still have no information in the labeling for use in pediatrics. The purpose of off-label use is to benefit the individual patient. Practitioners use their professional judgment to determine these uses. As such, the term “off-label” does not imply an improper, illegal, contraindicated, or investigational use. Therapeutic decision-making must always rely on the best available evidence and the importance of the benefit for the individual patient. *Pediatrics* 2014;133:563–567

INTRODUCTION

The purpose of this statement is to further define and discuss the status of off-label use of medications in children. Since publication of the 2002 statement from the American Academy of Pediatrics on the off-label use of drugs,¹ the number of drugs approved by the US Food and Drug Administration (FDA) with pediatric indications or expanded labeling that informs drug use in pediatric patients (eg, pharmacokinetic/pharmacodynamic data, safety data) has substantially increased. The passage of the Best Pharmaceuticals for Children Act² (BPCA) and the Pediatric Research Equity Act³ (PREA) has resulted in more than 500 pediatric labeling changes. However, despite this success and advances in both basic science and clinical trials in pediatrics, off-label drug use remains a common and important issue for children and adolescents. Moreover, off-label use of drugs presents an even larger and more complex issue in preterm and full-term neonates, infants and in children younger than 2 years,⁴ and children with chronic and/or rare diseases.

DEFINING OFF-LABEL USE

The term “off-label” use refers to use of a drug that is not included in the package insert (approved labeling) for that drug. The purpose of off-label use is to benefit an individual patient. It is important to note that the term “off-label” does not imply an improper, illegal, contraindicated, or investigational use. To approve a drug for sale and marketing within the United States, the FDA requires substantial

evidence for efficacy and safety, usually in the form of 2 well-controlled trials. Subsequent requests by a sponsor to add a new indication to drug labeling must also be accompanied by additional evidence in support of that indication. If the FDA finds that such evidence supports approval, the new indication is added to the product labeling. If the evidence is deemed insufficient or if the sponsor chooses not to submit evidence, the indication is not added.

According to the Code of Federal Regulations,⁵ a sponsor is the entity that holds an investigational new drug application and that both takes responsibility for and initiates a clinical investigation. The sponsor may be an individual or pharmaceutical company, governmental agency, academic institution, private organization, or other organization. A sponsor does not actually conduct the investigation unless the sponsor is a sponsor-investigator. A person other than an individual who uses 1 or more of his or her own employees to conduct an investigation that he or she has initiated is considered to be a sponsor, not a sponsor-investigator. In this case, the employees are investigators. Sponsor-investigators both initiate and conduct an investigation and direct the administration or dispensing of the investigational drug. The requirements applicable to a sponsor-investigator include both those applicable to an investigator and a sponsor. It is important to note that sponsors are not allowed to promote or even speak to off-label use. If a physician speaks on behalf of a sponsor, the same rule applies. It is acceptable to use drugs off label and to publish results related to off-label use, but it is not acceptable to receive remuneration from the sponsor for these uses.

The absence of labeling for a specific age group or for a specific disorder does not necessarily mean that the

drug's use is improper for that age or disorder. Rather, it only means that the evidence required by law to allow inclusion in the label has not been approved by the FDA. Additionally, in no way does a lack of labeling signify that therapy is unsupported by clinical experience or data in children. Instead, it specifically means that evidence for drug efficacy and safety in the pediatric population has not been submitted to FDA for review or has not met the regulatory standards of "substantial evidence" for FDA approval. In contrast to the absence of pediatric-specific information on some medications, other drug labels contain statements such as "the safety and efficacy in pediatric patients have not been established," and explicit evidence-based warnings and contraindications are included on the label where indicated. Understanding the distinction between the lack of FDA approval for a particular use or dosing regimen in the former case versus explicit warnings or contraindications against use in the latter is essential for the pediatric practitioner. In addition, when considering best practices for therapeutic decision-making, it is essential to understand that the FDA does not regulate the use of drugs as they pertain to the practice of medicine.⁶

THE ROLE OF THE FDA

The FDA is the federal government agency charged with oversight responsibility for the manufacturing, labeling, advertisement, and safety of therapeutic drugs and biological products. The Food, Drug, and Cosmetic Act⁷ requires that "substantial evidence," resulting from "adequate and well-controlled investigations" demonstrating that a new drug "will have the effect it purports or is represented to have under the conditions of use prescribed, recommended, or suggested in the proposed labeling," be submitted to and reviewed and approved by the FDA

before the drug is marketed in interstate commerce. For drugs and biological agents (eg, vaccines, antibodies), proof of effectiveness consists of "adequate and well-controlled studies" as defined for new drugs in the Code of Federal Regulations.⁸ Biological agents are approved under the Public Health Service Act.⁹ Given these requirements as well as the rapid pace of medical discovery, it is not surprising that labeling does not reflect all possible uses of an agent. Off-label use of drugs in children is not overseen by the FDA, because the FDA does not regulate the prescription practices of individual practitioners.

The FDA maintains a system for post-marketing drug surveillance, compiling and analyzing information about the incidence and severity of adverse events reported by practitioners, sponsors, hospitals, and other health care facilities. It is important to note that this postmarket surveillance system is passive and that the total number of adverse event reports in pediatrics relative to adults is small. To address this issue, the BPCA provides for a systematized review of adverse event reports in pediatric patients through the FDA Pediatric Advisory Committee. When the FDA notes an apparent association between use of a drug and an adverse event, the FDA may choose from several actions: to request further focused study of the drug, to add a contraindication or warning to the drug labeling, to issue a warning about use of the drug, or to seek voluntary or compulsory removal of the drug from the market. Therefore, although the FDA does not regulate the practice of medicine, practitioners should be aware of new information brought forward by the FDA, because it can serve as a valuable resource for information regarding the potential or proven adverse effects of drugs (see www.fda.gov).

THERAPEUTIC DECISION-MAKING

Therapeutic decision-making should always be guided by the best available evidence and the importance of the benefit for the individual patient. Practitioners are in agreement regarding the importance of practicing evidence-based medicine. However, for the pediatric population, gold standard clinical trials are often not available, so practitioners must rely on either less definitive information, such as expert opinion for the age group that they are treating, or use evidence from a different population to guide practice. There are now many resources available to help assess the quality of evidence-based medicine, including but not restricted to articles in peer-reviewed journals, American Academy of Pediatrics practice guidelines and policy statements, consensus statements, and handbooks and databases (ie, Cochrane, Lexicomp, and Harriet Lane). At times, there may be little or no published information to guide therapy. This situation is especially true when treating rare diseases or sparse populations such as neonates. In such situations, the practicing physician can play an important role in adding to therapeutic information by publishing his or her experience with off-label uses of drugs. These reports can serve as the basis of more formal efficacy and safety studies and can serve as a therapeutic decision-making resource for other physicians. The practicing physician also has a responsibility to report adverse events to the FDA through the Medwatch program (www.fda.gov/Safety/MedWatch).

In most situations, off-label use of medications is neither experimentation nor research. The administration of an approved drug for a use that is not approved by the FDA is not considered research and does not warrant special consent or review if it is deemed to be in the individual patient's best interest.⁶

In general, if existing evidence supports the use of a drug for a specific indication in a particular patient, the usual informed-consent conversations should be conducted, including anticipated risks, benefits, and alternatives. If the off-label use is based on sound medical evidence, no additional informed consent beyond that routinely used in therapeutic decision-making is needed.¹⁰ However, if the off-label use is experimental, then the patient (or parent) should be informed of its experimental status.¹¹ It would be prudent for pediatricians to know and abide by the appropriate informed consent laws in their respective states. In addition, particular risk-benefit ratios presented by the unproven therapies must be carefully considered and disclosed, and standard of care practices should be reviewed. When use of a drug is truly investigational, drug use should be performed in conjunction with a well-designed clinical trial whenever possible. This is especially true when the physician proposes to treat a group of patients rather than a single individual. Patients and/or their legal guardians should be specifically informed that the proposed therapy is investigational, and their consent to proceed despite the risks of investigational therapy should be carefully documented. Whether institutional review, consultation, or written consent are required for a given intervention depends on the degree of risk or departure from standard practices and the extent to which research, rather than individual patient care, is involved.

Practitioners may be concerned that the off-label use of an approved drug may invite a variety of legal actions. To conform to accepted professional standards, the off-label use of a drug should be done in good faith, in the best interest of the patient, and without fraudulent intent. A practitioner

may be accountable for the negligent use of any drug in a civil action, regardless of whether the FDA has approved the use of that drug. Labeling is not intended to preclude the practitioner from using his or her best medical judgment in the interest of patients or to impose liability for off-label use. Indeed, the practice of medicine will more than likely require a practitioner to use drugs off label to provide the most appropriate treatment of a patient. However, because the use of drugs in an off-label capacity can increase the liability risk for a practitioner should an adverse event or poor outcome ensue, it is essential that practitioners document the decision-making process to use a drug off label in the patient's medical record.

FEDERAL LEGISLATION TO INCREASE DRUG TESTING IN CHILDREN

The BPCA and the PREA are 2 complementary federal laws that have substantially increased clinical evaluation and labeling of drugs in children both by the pharmaceutical industry and through government-sponsored trials.⁸ The PREA mandates that almost all new drugs and certain approved drugs must be studied in children for approved uses of the product if there is potential for use of that drug in children and that the application for new drug approval include the results of adequate pediatric studies unless the studies are deferred or waived by the FDA. The BPCA allows sponsors to qualify for an additional 6 months of market exclusivity if the sponsor completes and submits pediatric studies to the FDA, as outlined in an FDA-issued written request. A written request may include off-label as well as approved uses of a drug. In addition, the BPCA authorizes the National Institutes of Health, in conjunction with the FDA

and physicians from clinical disciplines, to work together to assign priority for testing of specific drugs in children. The National Institutes of Health, acting through the Eunice Kennedy Shriver National Institute of Child Health and Human Development, then solicits proposals for pediatric drug testing concordant with the drug prioritization recommendations and funds clinical studies that are judged meritorious by external review. The ratification of these 2 laws has been considered a significant success, because there have been more than 500 pediatric labeling changes. Also as a result of these laws, increased prospective pediatric drug testing has occurred via industry-sponsored studies, investigator-initiated studies, and consortia, such as the National Institute of Child Health and Human Development–funded Pediatric Trials Network. The net result has been an expansion of both pediatric labeling information and the knowledge base from which practitioners can draw to make informed therapeutic decisions.^{12,13}

In 2012, Congress passed the Food and Drug Administration Safety and Innovation Act,¹⁴ reauthorizing and strengthening the BPCA and PREA. The legislation aims to ensure that pediatric evaluations under PREA are conducted earlier in the drug development process to improve the quality of and accountability for completion of such studies and to advance the neonatal drug studies under the BPCA and PREA. The legislation also makes both the BPCA and PREA permanent law.

CONCLUSIONS

Off-label drug use remains an important public health issue, especially for infants, young children, and children with rare diseases. Evidence, not label indication, remains the gold standard from which practitioners should draw

when making therapeutic decisions for their patients. The PREA and BPCA have been extremely successful and represent an essential first step in expanding this evidence as a means of achieving the ultimate goal that any and all drugs used to treat children will have age-appropriate evidence sufficient to provide information for labeling. However, labeling with pediatric information still exists in less than 50% of products,¹⁵ such that much work remains to be done to ensure the best possible practice for therapeutic decision-making in pediatrics.

RECOMMENDATIONS

1. The practitioner who prescribes a drug is responsible for deciding which drug and dosing regimen the patient will receive and for what purpose.
 - a. This decision should be made on the basis of the information contained in the drug's labeling (when available) or other data available to the prescriber.
 - b. The use of a drug, whether off or on label, should be based on sound scientific evidence, expert medical judgment, or published literature whenever possible.
 - c. Off-label use is neither incorrect nor investigational if based on sound scientific evidence, expert medical judgment, or published literature.
2. Pediatricians should continue to advocate for necessary incentives and requirements to promote the study of drugs in children.
3. Physician researchers are encouraged to continue the rational and critical study of drugs in children through conducting and/or collaborating in well-designed pediatric drug studies, including national consortium studies.

4. Journals should be encouraged to publish the results of all well-designed investigations, including negative studies.
5. Institutions and payers should not use labeling status as the sole criterion that determines the availability on formulary or reimbursement status for medications in children. Similarly, less expensive therapeutic alternatives considered appropriate for adults should not automatically be considered appropriate first-line treatment in children. Finally, off-label uses of drugs should be considered when addressing various drug-related concerns, such as drug shortages.

abstract

FREE

The pediatrician plays a major role in helping optimize bone health in children and adolescents. This clinical report reviews normal bone acquisition in infants, children, and adolescents and discusses factors affecting bone health in this age group. Previous recommended daily allowances for calcium and vitamin D are updated, and clinical guidance is provided regarding weight-bearing activities and recommendations for calcium and vitamin D intake and supplementation. Routine calcium supplementation is not recommended for healthy children and adolescents, but increased dietary intake to meet daily requirements is encouraged. The American Academy of Pediatrics endorses the higher recommended dietary allowances for vitamin D advised by the Institute of Medicine and supports testing for vitamin D deficiency in children and adolescents with conditions associated with increased bone fragility. Universal screening for vitamin D deficiency is not routinely recommended in healthy children or in children with dark skin or obesity because there is insufficient evidence of the cost-benefit of such a practice in reducing fracture risk. The preferred test to assess bone health is dual-energy x-ray absorptiometry, but caution is advised when interpreting results in children and adolescents who may not yet have achieved peak bone mass. For analyses, z scores should be used instead of T scores, and corrections should be made for size. Office-based strategies for the pediatrician to optimize bone health are provided. This clinical report has been endorsed by American Bone Health. *Pediatrics* 2014;134:e1229–e1243

The antecedents of osteoporosis are established in childhood and adolescence, and the pediatrician plays a major role in helping optimize bone health in the pediatric age group. Osteoporosis, a disease of increased bone fragility, is a major cause of morbidity and economic burden worldwide. It is estimated that by the year 2020, one-half of Americans older than 50 years will be at risk for osteoporotic fractures.¹ Once thought to be an inevitable part of aging, osteoporosis is now considered to have its roots in childhood, when preliminary preventative efforts can be initiated. In fact, bone mass attained in early life is thought to be the most important modifiable determinant of lifelong skeletal health.² Osteoporosis is not restricted to adults; it can occur in children and adolescents. The aim of the present clinical report was to review bone acquisition during infancy, childhood, and adolescence; discuss assessment of bone health, particularly as it applies to children and adolescents; and update pediatricians on strategies to improve bone health in the pediatric age group. health needs of pregnant women, lactating mothers, and preterm infants are discussed elsewhere.^{3,4} This clinical report has been endorsed by American Bone Health, a national, community-based organization that provides education programs, tools, and resources to help the public understand bone disease and bone health.

BONE ACQUISITION DURING CHILDHOOD AND ADOLESCENCE

Bone is a living structure comprising a matrix of collagen, hydroxyapatite crystals, and noncollagenous proteins. The matrix becomes mineralized with deposits of calcium and phosphate, which confers strength to the structure. Bone mineral deposition begins during pregnancy, with two-thirds of in utero accrual occurring during the third trimester.⁵ Bone mineral content (BMC) increases 40-fold from birth until adulthood, and peak bone mass is achieved toward the end of the second decade of life, although there may still be some net bone deposition into the third decade.^{6–11} Approximately 40% to 60% of adult bone mass is accrued during the adolescent years, with 25% of peak bone mass acquired during the 2-year period around peak height velocity. After infancy, peak bone mineral accretion rates occur, on average, at 12.5 years for girls and 14.0 years for boys.¹² At age 18 years, approximately 90% of peak bone mass has been accrued.¹³ Childhood and adolescence, therefore, are critical periods for skeletal mineralization. Age of peak bone mass accrual lags behind age of peak height velocity by approximately 6 to 12 months in both boys and girls.¹² This dissociation between linear growth and bone mineral accrual may confer increased vulnerability to bone fragility and may explain, to some degree, the increased rate of forearm fractures in boys 10 through 14 years of age and

in girls 8 through 12 years of age.^{14,15} After peak bone mass is achieved, there is a slow but progressive decline in bone mass until a theoretical fracture threshold is reached. Any condition interfering with optimal peak bone mass accrual can, therefore, increase fracture risk later in life.

The skeleton is an active organ, constantly undergoing remodeling, even after linear growth has been completed. During remodeling, bone formation, mediated via osteoblasts, and bone resorption, mediated by osteoclasts, occur concurrently. Remodeling is regulated by local cytokines as well as by circulating hormones, including parathyroid hormone (PTH), 1,25-dihydroxyvitamin D (1,25-OH₂-D), insulin-like growth factor 1 (IGF-1), and calcitonin. In young children, the rate of cortical bone remodeling is as high as 50% per year. Net bone mass depends on the balance between bone resorption and bone formation. If formation exceeds resorption, as it should during childhood and adolescence, net bone mass increases. If resorption exceeds formation, net bone mass is reduced.

PRIMARY PREVENTION: OPTIMIZING BONE HEALTH IN HEALTHY CHILDREN

Factors affecting bone health are shown in Table 1. Genetic factors account for approximately 70% of the variance in bone mass,¹⁶ although no specific responsible genes have been identified. Male subjects have higher bone mass than female subjects, and black women have higher bone mass than white non-Hispanic women or Asian women. Mexican-American women have bone densities between those of white non-Hispanic and black women. Modifiable determinants of bone mass include nutritional intake of calcium, vitamin D, protein, sodium, and carbonated beverages (ie, soda); exercise and lifestyle;

maintenance of a healthy body weight, and hormonal status. Nutrition and physical activity are each necessary and function synergistically to improve bone acquisition and maintenance.

CALCIUM

Calcium is necessary for bone accretion, and dietary calcium intake during infancy, childhood, and adolescence affects bone mass acquisition. Approximately 99% of total body calcium is found in the skeleton, and calcium is absorbed by both passive and active transport, the latter mediated by vitamin D. Milk intake during childhood and adolescence is associated with higher BMC and reduced fracture risk in adulthood.¹⁷ The Institute of Medicine (IOM) has published updated dietary reference intakes for calcium and vitamin D, and the American Academy of Pediatrics (AAP) endorses these recommendations for infants, children, and adolescents (Table 2).¹⁸ The recommended dietary allowance (RDA) is the dietary intake that meets the requirements of almost all (97.5%) of the population. Adequate intake is a single value likely to meet the needs of most children and is used for infants younger than 12 months, for whom RDAs have not been established. The upper limit represents the highest average total daily intake likely to pose no risk

of adverse health effects for most people in that age group.

Sources of Calcium

Term Infants and Children

The primary source of nutrition for healthy term infants in the first year of life is human milk or, alternatively, infant formula if human milk is not available. Although the BMC may be higher in formula-fed infants than in breastfed infants in the first year of life, the breastfed infant does not demonstrate any evidence of clinical mineral deficiency, and there is no evidence that the breastfed infant should not be the standard for bone mineral accretion. No data support high mineral intake or supplementation with calcium for healthy breastfed infants.¹⁹ After the first year of life, the major source of dietary calcium is milk and other dairy products, which together account for 70% to 80% of dietary calcium intake. Each 8-oz (240-mL) serving of milk provides approximately 300 mg of calcium, and the calcium content of low-fat or flavored milk is similar to that of whole milk (Table 3).²⁰ However, low-fat chocolate milk contains added sugar and more calories than does low-fat plain milk. One cup of yogurt or 1.5 oz of natural cheese each provides approximately 300 mg of calcium. Other dietary sources of calcium include green leafy vegetables, legumes, nuts, and calcium-fortified breakfast

cereals and fruit juices. Vegetables contributed approximately 7% of the calcium in the food supply between 2000 and 2006.²¹ Bioavailability of calcium from vegetables is generally high but is reduced by binding with oxalates in spinach, collard greens, rhubarb, and beans. Although vegetables are a good source of bioavailable calcium, the quantity of vegetables required to meet daily requirements is substantial, making it difficult to attain dietary calcium requirements with vegetables alone. Certain cereals (eg, whole bran cereals) contain phytates, which also reduce bioavailability.

Preadolescents and Adolescents

The calcium RDA for preadolescents and adolescents aged 9 through 18 years is 1300 mg/d. In the United States, the average dietary calcium intake of adolescent girls is 876 mg/d (67% of the RDA), and less than 15% meet the RDA.²² In 2011, only 14.9% of high school students drank three or more 8-oz servings of milk per day, with only 9.3% of girls doing so.²³ Milk consumption by adolescents has declined at the same time that soda consumption has increased.²⁴ Some adolescent girls avoid milk products because they consider them to be “fattening.” Such myths should be dispelled. For example, one 8-oz serving of skim milk contains no fat and only approximately 80 kcal, approximately the same caloric content

as an apple. In contrast, a can of soda contains 140 kcal. Furthermore, milk provides protein and a number of important nutrients other than calcium, including vitamin D, phosphorus, and magnesium, which are important in bone health. Milk alternatives, such as soy- or almond-based beverages, may have a reduced amount of bioavailable calcium per glass, even when fortified with calcium.²⁵ Further research is needed regarding the mineral levels and bioavailability of these beverages.

Lactose intolerance occurs in children and adolescents and is more common in black, Hispanic, and Asian subjects. Some of these children and adolescents will be able to tolerate small amounts of dairy products other than milk. Others may benefit from lactose-reduced or lactose-free milks and cheeses and/or lactase enzymes.²⁶

Calcium Supplementation

Although a number of studies have demonstrated a positive effect of calcium supplementation on BMC in healthy children and adolescents,^{27,28} a recent meta-analysis of randomized controlled trials examining the effectiveness of calcium supplementation in increasing BMD in healthy children found that there was no effect of calcium supplementation on BMD of the lumbar spine or femoral neck; a small effect was noted on upper-limb BMD and total body BMC equivalent to approximately

TABLE 2 Calcium and Vitamin D Dietary Reference Intakes

Age	Calcium		Vitamin D

a 1.7% increase in bone mass.²⁹ The investigators concluded that, from a public health perspective, calcium supplementation of healthy children is unlikely to result in a clinically significant reduction in fracture risk. For most children and adolescents, the emphasis should be on establishing healthy dietary behaviors with a well-balanced diet that includes calcium intake at or near the recommended levels throughout childhood and adolescence. Dietary sources of calcium should be recommended in preference to calcium supplements, not only because of the improved bioavailability of dietary sources of calcium, but also primarily to encourage lifelong healthy dietary habits.

VITAMIN D

Vitamin D (calciferol) is a fat-soluble hormone necessary for calcium absorption and utilization. Without vitamin D, only 10% to 15% of dietary calcium is absorbed.³⁰ Vitamin D includes endogenous conversion of vitamin D₂, ingested animal-derived cholecalciferol (vitamin D₃), and plant-derived ergocalciferol (vitamin D₂). Although there is increasing evidence that vitamin D may also have potential benefits on cardiometabolic risk factors, immunity, and cancer prevention, the focus of the present report is on bone health.

In 2011, the IOM revised the RDAs for vitamin D intake to be higher than previous recommendations (Table 2), and

the AAP endorsed these recommendations.³¹ Vitamin D deficiency results in rickets in young children (peak incidence: 3–18 months of age) and increased fracture risk in older children, adolescents, and adults. Deficiency is particularly common in those living in northern climates, those with dark skin, and those with inadequate exposure to sunlight, but deficiency also occurs in sunny climates.^{32,33} National US data reveal higher rates of vitamin D deficiency in adolescents compared with younger children³⁴ and increasing prevalence from the 1988–1994 to 2001–2004 data collections.³⁵ Cross-sectional studies of vitamin D status in adolescents have found deficiency in 17% to 47% of adolescents,^{32,33,36,37} with increased risk in black and Hispanic teenagers^{33,37,38} and lower vitamin D concentrations in the winter.^{36–38} Children and adolescents who are obese are at increased risk,^{33,39,40} possibly because of sequestration of vitamin D in body fat. Certain medications, such as anticonvulsant, glucocorticoid, antifungal, and antiretroviral medications, increase requirements and predispose subjects to deficiency. Severe vitamin D deficiency is associated with reduced bone mass in adolescents.^{41,42} On the basis of results of a longitudinal prospective study of 6712 physically active girls aged 9 through 15 years, vitamin D intake—not calcium or dairy intake—during childhood is associated with reduced risk of stress fractures.⁴³

Vitamin D₃ is synthesized in the skin from 7-dehydrocholesterol on exposure to sunlight, binds to vitamin D-binding protein, and is transported to the liver where it undergoes hydroxylation to form 25-hydroxyvitamin D (25-OH-D). The half-life of 25-OH-D is 2 to 3 weeks, and serum 25-OH-D is a good indicator of vitamin D stores. Circulating 25-OH-D undergoes a second round of hydroxylation in the kidney to form 1,25-OH₂D, the active form of the hormone. In

contrast to 25-OH-D, 1,25-OH₂-D has a half-life of 4 hours.⁴⁴ Under control of PTH, 1,25-OH₂-D promotes intestinal absorption of calcium and phosphorus, increases renal reabsorption of filtered calcium, and mobilizes calcium from skeletal stores.

Sources of Vitamin D

Sunlight

Exposure to UV B radiation in the range of 290 to 315 nm from sunlight is the major source of vitamin D. Synthesis of vitamin D depends on latitude, skin pigmentation, sunscreen use, and time of day of exposure. Synthesis of vitamin D is minimal during winter months north of 33° latitude in the northern hemisphere and south of 33° latitude in the southern hemisphere. Exposure of arms and legs to 0.5 minimal erythral dose of sunlight for 5 to 15 minutes, 2 to 3 times a week, produces approximately 3000 IU of vitamin D.³¹ Subjects with dark skin require exposure 3 to 5 times longer. Sunscreen with a sun protection factor 8 or higher effectively prevents transmission of UV B radiation through the skin and blocks the synthesis of vitamin D₃. Maximal synthesis occurs between the hours of 10:00 AM and 3:00 PM in the spring, summer, and fall.⁴⁵ Children and adolescents are spending more time indoors and, because of concerns regarding skin cancer later in life, when they do go outside, they often wear sun protection, which limits the skin's ability to synthesize vitamin D. With decreased synthesis of vitamin D from reduced sun exposure, dietary sources of vitamin D become more important.

Dietary Sources

Natural dietary sources of vitamin D are limited but include cod liver oil, fatty fish (eg, salmon, sardines, tuna), and fortified foods. Farm-raised salmon has lower concentrations of vitamin D than does fresh, wild-caught salmon.³¹ Human milk does not provide adequate amounts of vitamin D (approximately

20 IU/L). In the United States and Canada, all infant formula is fortified with vitamin D. Cow milk, infant formula, and fortified fruit juices each contain approximately 100 IU of vitamin D per 8 oz (Table 4).

Recommended Daily Intake and Vitamin D Supplementation

Adequate vitamin D intake for infants younger than 1 year is 400 IU/d. The RDA is 600 IU for children 1 year and older. Because human milk contains inadequate amounts of vitamin D (unless the lactating mother is taking supplements of approximately 6000 IU/d), breastfed and partially breastfed infants should be supplemented with 400 IU of vitamin D per day beginning in the first few days of life and continued until the infant has been weaned and is drinking at least 1 L/d of vitamin D-fortified infant formula or cow milk. Daily supplementation of breastfed infants with 400 IU of vitamin D during the first months of life increases 25-OH-D amounts to normal concentrations.^{46,47} Although the RDA

for children older than 1 year and for adolescents is 600 IU, children who are obese and children on anticonvulsant, glucocorticoid, antifungal, and anti-retroviral medications may require 2 to 4 times the recommended dose of vitamin D to achieve serum 25-OH-D values the same as children without these conditions; at this time, however, definitive recommendations for these children remain unavailable.

Although approximately 98% of cow milk in the United States is fortified with vitamin D, some yogurts, cheeses, juices, and breakfast cereals are also fortified with similar amounts of vitamin D (Table 4) and can generally be recommended in preference to nonfortified foods. For those who are unable to achieve adequate amounts of vitamin D in their diet or who have vitamin D deficiency, vitamin D supplements are available in 2 forms: vitamin D₂ (ergocalciferol), derived from plants, and vitamin D₃ (cholecalciferol), synthesized by mammals. Drisdol (Sanofi-Aventis US,

^b Not all brands of orange juice, yogurt, and cheese are fortified with vitamin D.

Bridgewater, NJ) is a vitamin D₂ preparation that contains 8000 IU/mL, and most multivitamins contain 400 IU per tablet. Some calcium preparations also contain vitamin D. In adolescent girls, supplementation of 200 to 400 IU of vitamin D₃ was effective in increasing BMD in a dose-response manner.⁴⁸ The daily upper limits are as follows: infants up to 6 months of age: 1000 IU; infants 6 to 12 months of age: 1500 IU; children 1 through 3 years of age: 2500 IU; children 4 through 8 years of age: 3000 IU; and children and adolescents 9 through 18 years of age: 4000 IU (Table 2).

Assessment of Vitamin D Status

Measurement of serum 25-OH-D concentration reflects both endogenous synthesis and dietary intake of vitamin D and is the optimal method of assessment of vitamin D status.⁴⁵ The 2011 RDAs were selected to ensure that nearly all those who receive the RDA will have a serum 25-OH-D concentration greater than 20 ng/mL. This value was derived on the basis of an assumption of minimal exposure to sunlight and minimal solar vitamin D conversion. The 25-OH-D concentration of 20 ng/mL was also set as a target by the Pediatric Endocrine Society and the European Society for Paediatric Gastroenterology, Hepatology and Nutrition.^{44,49} In contrast, the Endocrine Society has defined vitamin D deficiency as a 25-OH-D concentration <20 ng/mL (50 nmol/L) and insufficiency as a 25-OH-D concentration between 21 and 29 ng/mL (52.3–72.5 nmol/L).⁴⁵ Controversy remains as to whether there are specific health benefits to a higher target, such as 30 ng/mL or higher, for healthy children. In a population of healthy white Danish and Finnish girls, a daily intake of approximately 750 IU of vitamin D was necessary to enable 97.5% of the subjects to achieve a 25-OH-D concentration above 20 ng/mL, in support of the IOM recommendations.⁵⁰

Screening for Vitamin D Deficiency

Evidence is insufficient to recommend universal screening for vitamin D deficiency. The Endocrine Society recommends that “at-risk individuals” should be screened; these include children with obesity, black and Hispanic children, children with malabsorption syndromes, and children on glucocorticoid, anticonvulsant, antifungal, and antiretroviral medications.⁴⁵ There is concern, however, with these recommendations, because they would involve screening, treating, and retesting large numbers of children without good evidence of the cost–benefit in reducing fracture risk (as opposed to improving serum 25-OH-D concentrations) in a healthy population.⁵¹ For example, black youth have lower 25-OH-D concentrations than do white youth, but black subjects also have higher bone mass and reduced fracture risk. The IOM and existing AAP reports do not make recommendations specific to screening. In the absence of evidence supporting the role of screening healthy individuals at risk for vitamin D deficiency in reducing fracture risk and the potential costs involved, the present AAP report advises screening for vitamin D deficiency only in children and adolescents with conditions associated with reduced bone mass and/or recurrent low-impact fractures. More evidence is needed before recommendations can be made regarding screening of healthy black and Hispanic children or children with obesity. The recommended screening is measuring serum 25-OH-D concentration, and it is important to be sure this test is chosen instead of measurement of the 1,25-OH₂-D concentration, which has little, if any, predictive value related to bone health.

Treatment of Vitamin D Deficiency

Both vitamin D₂ and vitamin D₃ increase serum 25-OH-D concentrations. In adults, some^{52,53} but not all⁵⁴ studies

have suggested that vitamin D₃ is more effective in increasing serum 25-OH-D concentrations than is vitamin D₂. In infants and toddlers, 2000 IU of vitamin D₂ daily, 2000 IU of vitamin D₃ daily, and 50 000 IU of vitamin D₂ weekly were equivalent in increasing serum 25-OH-D concentrations.⁵⁵ Infants and toddlers with vitamin D deficiency can be given 50 000 IU of vitamin D₂ or vitamin D₃ weekly for 6 weeks or 2000 IU of vitamin D₂ or vitamin D₃ daily for 6 weeks, followed by a maintenance dose of 400 to 1000 IU/d. Children and adolescents can be treated with vitamin D₂ or vitamin D₃ (50 000 IU, 1 capsule weekly) for 6 to 8 weeks or 2000 IU of vitamin D₂ or vitamin D₃ daily for 6 to 8 weeks to achieve a serum 25-OH-D concentration greater than 20 ng/mL, followed by a maintenance dose of 600 to 1000 IU/d (Table 5).^{18,45} After completion of treatment, repeat serum 25-OH-D concentrations should be obtained. It is not unusual for a second course of treatment to be necessary to achieve adequate concentrations of serum 25-OH-D. There is no strong evidence about whether to treat healthy children who have serum 25-OH-D concentrations between 21 and 29 ng/mL.

SODA CONSUMPTION, PROTEIN, AND OTHER MINERALS

In 2010, 24.3% of US high school students drank at least 1 serving of soda daily.⁵⁶ A recent meta-analysis of 88 studies reported that soda consumption is associated with lower intake of milk and calcium, and larger effect sizes were found with longitudinal and experimental studies compared with cross-sectional studies. The replacement of milk in the diet by soda can prevent adolescents from achieving adequate calcium and vitamin D intake, and because soda consumption has no health benefit, it should be avoided.⁵⁷

Diets low in protein or high in sodium will predispose subjects to reduced

calcium retention.^{58,59} Sodium and calcium share the same transport system in the proximal tubule, and a high-sodium diet promotes increased urinary calcium excretion and should be avoided.

EXERCISE AND LIFESTYLE

Mechanical forces applied to the skeleton (mechanical loading) increase bone formation, and weight-bearing exercise improves bone mineral accrual in children and adolescents.⁶⁰ In healthy children, an exercise program incorporating high-impact, low-frequency exercises such as jumping, skipping, and hopping for 10 minutes 3 times a week increased BMD of the femoral neck in the intervention group compared with control subjects.^{61–63} The greatest effect was observed in children in early puberty. A population-based prospective controlled trial in Sweden demonstrated that a school-based, moderately active, 4-year exercise program increased bone mass and size in children aged 7 through 9 years without increasing fracture risk.⁶⁴ Adolescent female athletes have higher BMD than nonathletes, provided they are menstruating regularly. When female athletes become amenorrheic, the protective effect of exercise on BMD is lost.⁶⁵ Children who are immobilized have rapid declines in bone mass.

Increases in BMD are site specific, depending on the loading patterns of the specific sport. For example, BMD is greater in gymnasts at the hip and spine, in runners at the femoral neck, and in rowers at the lumbar spine; tennis players have higher radial BMD in the

dominant arm than in the nondominant arm. High-impact sports (eg, gymnastics, volleyball, karate) or odd-impact sports (eg, soccer, basketball, racquet sports) are associated with higher BMD and enhanced bone geometry.⁶⁶

For most children and adolescents, walking, jogging, jumping, and dancing activities are better for bone health than are swimming or bicycle riding. Excessive high-impact exercise can, however, increase fracture risk. A prospective longitudinal study of 6831 high school girls found that those who participated in more than 8 hours per week of running, basketball, cheerleading, or gymnastics were twice as likely to sustain a fracture compared with less active girls. The authors suggested that girls who participate in these sports should also include cross-training in lower impact activities.⁶⁷

Lifestyle choices may also confer additional risk for BMD deficits. In adults, smoking, caffeine, and alcohol intake are all associated with reduced BMD,^{68–70} and these behaviors should be avoided in children and adolescents.

BODY WEIGHT

Body weight and composition are important modifiable determinants of bone mass. Mechanical loading during weight-bearing activities stimulates bone formation, and multiple studies in healthy adolescents^{8,71–73} and in those with anorexia nervosa^{74–77} have demonstrated that BMD is directly correlated with BMI. Lean body mass is most strongly associated with BMD,⁷⁸ but increased adiposity can also be associated with

increased fracture risk.⁷⁹ Maintenance of a healthy body weight during childhood and adolescence is therefore recommended to optimize bone health.

HORMONAL STATUS

Several hormones affect bone mass. Estrogen plays an important part in maintaining BMD in women, and estrogen deficiency is associated with increased bone resorption and increased fracture risk. Testosterone, growth hormone, and IGF-1 all promote bone formation, whereas glucocorticoid excess both increases bone resorption and impairs bone formation.

**SECONDARY PREVENTION:
ASSESSMENT OF POPULATIONS AT
RISK FOR INCREASED BONE
FRAGILITY**

**Conditions Associated With
Reduced Bone Mass in Children
and Adolescents**

Conditions associated with reduced bone mass and increased fracture risk in children and adolescents are listed in Table 6. Osteogenesis imperfecta, idiopathic juvenile osteoporosis, and Turner syndrome are rare conditions with increased bone fragility, best managed by pediatric endocrinologists, geneticists, and specialists in pediatric bone health. Children with chronic illnesses are, however, frequently managed by general pediatricians. Cystic fibrosis, systemic lupus erythematosus, juvenile idiopathic arthritis, inflammatory bowel disease, celiac disease, chronic renal failure, childhood cancers, and cerebral palsy

Age	Preparation and Dose ^a	
Infants, 0–12 mo	Vitamin D ₂ or D ₃ 50 000 IU weekly for 6 wk Followed by a maintenance dose of 400–1000 IU daily	or Vitamin D ₂ or D ₃ 2000 IU daily for 6 wk
Children and adolescents, 1–18 y	Vitamin D ₂ or D ₃ 50 000 IU weekly for 6–8 wk Followed by a maintenance dose of 600–1000 IU daily	or Vitamin D ₂ or D ₃ 2000 IU daily for 6–8 wk

Vitamin D₂, ergocalciferol; vitamin D₃, cholecalciferol.

^a Vitamin D₃ may be more potent than vitamin D₂.

can all be associated with reduced bone mass.^{78,80–84} Risk factors include malnutrition, increased metabolic requirements, intestinal malabsorption, low body weight, chronic inflammation with increased cytokine production, hypogonadism, immobilization, and the effects of prolonged glucocorticoid therapy. Children with cerebral palsy are at particular risk. One study found that 77% of children with cerebral palsy had a femoral neck BMD z score less than –2.0, and 26% of children older than 10 years had sustained a fracture.⁸⁴

Eating disorders are prevalent in adolescents.⁸⁵ Anorexia nervosa is associated with reduced BMD and increased fracture risk,^{74–76,86–89} and the reduction in bone mass occurs after a relatively short duration of illness.^{74,90} Etiologic

factors include poor nutrition, low body weight, estrogen deficiency, and hypercortisolism. The degree of reduction of BMD is directly related to the degree of malnutrition, and in girls, is related to the duration of amenorrhea. Low BMD is also found in boys with anorexia nervosa and is associated with low testosterone concentrations.⁹¹ Patients with partial eating disorders or those with bulimia nervosa may also have reduced bone mass, especially if they are or have been of low weight.^{89,92,93} The “female athlete triad” refers to 3 interrelated conditions seen in female athletes: low energy availability, menstrual dysfunction, and reduced BMD.⁹⁴ Low energy availability refers to inadequate energy intake for the level of physical activity. The energy deficit may be unintentional secondary to a lack of knowledge regarding the increased energy requirements of athletes or it may be intentional and associated with an underlying eating disorder. There is suppression of the hypothalamic-pituitary-ovarian axis, resulting in amenorrhea, a low estrogen state, reduced bone mass, and increased fracture risk.

Endocrine conditions associated with glucocorticoid or PTH excess, hypogonadism, hyperthyroidism, or deficiency of growth hormone or IGF-1 are all associated with low bone mass (Table 6). Certain medications, including anticonvulsants and chemotherapeutic agents, prolonged use of proton pump inhibitors, and selective serotonin reuptake inhibitors, can also have a negative effect on bone mass. Depot medroxyprogesterone acetate (DMPA) is a very effective long-acting contraceptive that has been credited, to some degree, for the reduction in adolescent pregnancy rates in the United States over the past decade. Prolonged use of DMPA in adolescent girls is associated with hypothalamic suppression and reduced bone mass, however.⁹⁵ In 2004, the US Food and

Drug Administration issued a black box warning to inform practitioners about the negative effects of DMPA on bone mass. Discontinuation of DMPA is associated with rapid improvements in bone mass, although it is not known how much of potential maximum peak bone mass is recovered.⁹⁶ For most adolescents, the risk of fracture while taking DMPA is low, and the benefit of taking the medication outweighs the risks. The Society for Adolescent Health and Medicine recommends continuing to prescribe DMPA to adolescent girls needing contraception but recommends explanation of the risks and benefits.⁹⁷ The American College of Obstetrics and Gynecology further states that concerns about the effect of DMPA on BMD should neither prevent practitioners from prescribing it nor limit its use to 2 consecutive years.⁹⁸ In adolescent girls, low-dose oral contraceptives containing less than 30 µg of ethinyl estradiol may interfere with peak bone mass acquisition compared with oral contraceptives containing ≥30 µg of ethinyl estradiol.^{99,100} Despite a possible reduction in BMD in oral contraceptive users, a recent Cochrane review of observational studies found no association between oral contraceptive use and increased fracture risk.¹⁰¹

Assessment of Bone Health

The ideal method of assessment of clinically relevant bone health is determination of fracture risk on the basis of longitudinal data. However, there is a paucity of longitudinal studies examining factors affecting bone health in children on the basis of incidence of fractures. Fracture risk depends not only on skeletal fragility but also on age, body weight, history of fractures, and the force of an injury. Skeletal fragility, in turn, is dependent on a number of factors in addition to bone mass, including bone size, geometry, microarchitecture, and bending strength. For example, bending strength depends on the radius of a bone,

TABLE 6 Conditions Associated With Reduced Bone Mass in Children and Adolescents

Genetic conditions
Osteogenesis imperfecta
Idiopathic juvenile osteoporosis
Turner syndrome
Chronic illness
Cystic fibrosis
Connective tissue disorders (lupus, juvenile idiopathic arthritis, juvenile dermatomyositis)
Inflammatory bowel disease, celiac disease
Chronic renal failure
Childhood cancer
Cerebral palsy
Chronic immobilization
Eating disorders, including anorexia nervosa, bulimia nervosa, eating disorders not otherwise specified, and the female athlete triad
Endocrine conditions
Cushing syndrome
Hypogonadism
Hyperthyroidism
Hyperparathyroidism
Growth hormone deficiency
Diabetes mellitus
Medications
Glucocorticoids
Anticonvulsants
Chemotherapy
Leuprolide acetate
Proton pump inhibitors
Selective serotonin reuptake inhibitors
DMPA

and a large bone will be more resistant to fracture than a smaller bone, even when both bones have the same BMC or BMD. Bone mass, which accounts for approximately 70% of bone strength, can be used as a surrogate measure of bone health, recognizing that a low bone mass in children does not necessarily translate to increased fracture risk.

Dual-energy x-ray absorptiometry (DXA) is the preferred method of assessment of bone mass because of its availability, speed, precision, and low dose of radiation (5–6 mSv for the lumbar spine, hip, and whole body, which is less than the radiation exposure of a transcontinental flight and one-tenth that of a standard chest radiograph).¹⁰² DXA measures BMC and calculates areal BMD by dividing BMC by the area of the region scanned. DXA machines are widely available, and robust pediatric reference databases for children older than 5 years are included with the software of the major DXA manufacturers.^{103–106} In pediatric patients, the preferred sites of measurement are the lumbar spine and whole body.¹⁰⁷ In children, the hip is less reliable because of variability in positioning and difficulties identifying bony landmarks. Scanning time of the hip or spine is less than 1 minute; for the whole body, it is approximately 5 minutes. In adults, each SD reduction in BMD below the young adult mean doubles the fracture risk. Osteoporosis is operationally defined as a BMD 2.5 or more SDs below the young adult mean (a T score less than –2.5), and osteopenia is defined as a BMD ≥ 1 SD below the young adult mean (a T score of less than –1.0). However, caution should be used in interpreting DXA results in children. First, because children have not yet achieved peak bone mass, z scores (the number of SDs below the age-matched mean) should be used instead of T scores. Second, DXA measures 2-dimensional areal BMD (expressed as grams per square centimeter), as

opposed to 3-dimensional volumetric BMD (expressed in grams per cubic centimeter), and areal BMD underestimates true volumetric BMD in subjects with smaller bones. Third, many children with chronic illness have growth retardation and delayed puberty. Therefore, a correction should be made for height or height age, and a number of mathematical corrections have been proposed.^{108–110}

The International Society for Clinical Densitometry recommends that the term “osteopenia” no longer be used in pediatric DXA reports and that the diagnosis of osteoporosis not be made on the basis of DXA results alone.¹⁰⁷ In the pediatric age group, the diagnosis of osteoporosis requires both a low BMD or BMC (defined as a z score less than –2) and a clinically significant fracture (defined as a long-bone fracture of the lower extremity, a vertebral compression fracture, or 2 or more long-bone fractures of the upper extremity).^{107,111} Longitudinal studies in children and adolescents have demonstrated a high degree of tracking over a period of 3 years.¹¹² In other words, children with low bone density continue to have low bone density over time. In contrast to adults, in pediatrics, there is no specific BMD z score below which fractures are more likely to occur, but there is a growing body of literature demonstrating an association between low bone mass measured by using DXA and fracture risk in children.^{113–115}

Limited evidence is available to guide pediatricians regarding when to order a DXA. In general, a DXA should be performed to identify children and adolescents at risk for skeletal fragility fractures and to guide treatment decisions. The AAP’s “Clinical Report—Bone Densitometry in Children and Adolescents” recommends ordering a DXA for children and adolescents with clinically significant fractures (defined earlier) sustained after minimal trauma

(defined as falling from standing height or less) and in those with medical conditions associated with increased fracture risk.¹¹⁶ Evidence is insufficient to support obtaining a DXA in children and adolescents taking medications that can adversely affect bone or in healthy children with recurrent traumatic fractures of the fingers or toes. DXA scans are usually repeated after 1 year and should not be repeated at an interval of less than 6 months.

Quantitative computed tomography measures true volumetric BMD, but the radiation exposure dose is high (30–7000 mSv). Newer modalities, such as peripheral quantitative computed tomography, can measure volumetric BMD of the appendicular skeleton with much lower radiation doses but are not widely available for clinical use. Quantitative ultrasonography is a noninvasive method of assessing bone health by measuring speed of an ultrasound wave as it is propagated along the surface of bone. This method is difficult to interpret because of a lack of pediatric reference data, however, and poor precision in the pediatric population.

TERTIARY PREVENTION: SPECIFIC TREATMENTS TO INCREASE BONE MASS IN POPULATIONS AT INCREASED RISK OF FRACTURE

In most chronic diseases associated with low BMD, treatment of the underlying condition helps improve bone mass, and specific interventions will depend on the underlying condition.

Calcium Supplementation

Depending on the medical condition, for those children and adolescents who are unable to consume enough calcium from dietary sources, including fortified foods, calcium supplementation can be prescribed. The most common forms of supplemental calcium are calcium carbonate (40% elemental calcium) and calcium citrate (21% elemental calcium).

Calcium carbonate should be taken with meals to promote absorption, but calcium citrate does not require gastric acid for absorption and can be taken on an empty stomach.¹¹⁷ Calcium supplements are available in liquid, tablet, and chewable preparations.

Treatment of Vitamin D Deficiency

Screening for vitamin D deficiency by obtaining a serum 25-OH-D concentration is recommended in patients at increased risk of bone fragility and in those with recurrent low-impact fractures. Although a serum 25-OH-D concentration of 20 ng/mL is considered normal for healthy children and adolescents, some experts aim for achievement of a serum 25-OH-D concentration above 30 ng/mL in populations at increased risk of fracture, given the potential benefits and unlikely risk of toxicity of doses required to achieve this concentration (the upper limit for a child older than 9 years is 4000 IU/d).¹¹⁸ Pediatric treatment regimens for vitamin D deficiency are outlined in Table 5.

Bisphosphonates

Bisphosphonates inhibit osteoclast-mediated bone resorption and have been used to increase BMD and reduce fracture risk in children with osteogenesis imperfecta,^{119–121} cerebral palsy,¹²² and connective tissue disorders^{123,124} and children treated with corticosteroids.^{123,125–127} Pilot studies have also been conducted in adolescents with anorexia nervosa.¹²⁸ In osteogenesis imperfecta, an open-label study examining the use of cyclic administration of intravenous pamidronate reported reduced pain and fractures associated with dramatic increases in BMD.¹¹⁹ A recent multicenter, randomized controlled trial found increases in lumbar spine BMD (51% vs 12% in control subjects) with oral alendronate but no significant change in fracture incidence.¹²¹ Use of bisphosphonates in children remains controversial because

of the potential adverse effects of these agents and their long half-lives. Bisphosphonates are incorporated into bone and may be slowly released from the bone even after the medication has been discontinued. Because of the paucity of studies on efficacy and long-term safety, at this time these agents should not be used to treat asymptomatic reduction in bone mass in children, and their use should be restricted to osteogenesis imperfecta and other select conditions with recurrent fractures, severe pain, or vertebral collapse.^{129,130}

Oral Contraceptives

Adolescent girls with anorexia nervosa or the female athlete triad are frequently prescribed oral contraceptives to improve bone mass, even with no evidence of their efficacy.¹³¹ Prospective cohort studies and randomized controlled trials have both shown that oral contraceptives do not increase bone mass in subjects with anorexia nervosa or in female athletes.^{75,132–135} Because of this lack of demonstrated efficacy, their use is not recommended to increase bone mass. In girls with anorexia nervosa, oral contraceptives will induce monthly menstruation, which may be incorrectly interpreted as an indication of adequate weight restoration.

THE ROLE OF THE PEDIATRICIAN

1. Ask about dairy intake, nondairy sources of calcium and vitamin D, use of calcium and/or vitamin D supplements, soda consumption, and type and amount of exercise at health maintenance visits. Suggested ages to ask these questions are 3 years, 9 years, and during the annual adolescent health maintenance visits.
2. Encourage increased dietary intake of calcium- and vitamin D-containing foods and beverages. Dairy products constitute the major source of dietary calcium, but calcium-fortified

drinks and cereals are available. Low-fat dairy products, including nonfat milk and low-fat yogurts, are good sources of calcium. Children 4 through 8 years of age require 2 to 3 servings of dairy products or equivalent per day. Adolescents require 4 servings per day (Table 3). Suggested targeted questions include: “What kind of milk or dairy products do you consume?” “How many servings do you consume a day?” (One serving is an 8-oz glass of milk, an 8-oz yogurt, or 1.5 oz of natural cheese.) “In addition to dairy, what calcium-fortified foods do you buy or have you thought about buying?” Current data do not support routine calcium supplementation for healthy children and adolescents. The RDA of vitamin D for children 1 year and older is 600 IU. Children who are obese and children on anticonvulsant, glucocorticoid, antifungal, or retroviral medications may require higher doses, but specific end points and targets remain poorly defined.

3. Encourage weight-bearing activities. Walking, jumping, skipping, running, and dancing activities are preferable to swimming or cycling to optimize bone health.
4. Routine screening of healthy children and adolescents for vitamin D deficiency is not recommended. Those with conditions associated with reduced bone mass (Table 6) or recurrent low-impact fractures should have a serum 25-OH-D concentration measured. Those who have vitamin D deficiency should be treated and have 25-OH-D concentrations measured after completion of treatment.
5. Consider a DXA in medical conditions associated with reduced bone mass and increased bone fragility and in children and adolescents with clinically significant fractures sustained after minimal trauma. In

children, z scores should be used instead of T scores. In those with growth or maturational delay, corrections should be made for height or height age.

6. In adolescent female subjects, discourage preoccupation with extreme thinness. A DXA should be considered in an adolescent athlete who has been amenorrheic for more than 6 months. Athletes, parents, and coaches should be educated about the female athlete triad. There is no evidence to support prescribing oral contraceptives to increase bone mass in those with anorexia nervosa or the female athlete triad.
7. Until more studies demonstrating safety and efficacy in other popula-

tions have been conducted, use of bisphosphonates in children and adolescents should be restricted to osteogenesis imperfecta and conditions associated with recurrent fractures, severe pain, or vertebral collapse.

CLINICAL REPORT

Out-of-Home Placement for Children and Adolescents With Disabilities

abstract

FREE

The vast majority of children and youth with chronic and complex health conditions who also have intellectual and developmental disabilities are cared for in their homes. Social, legal, policy, and medical changes through the years have allowed for an increase in needed support within the community. However, there continues to be a relatively small group of children who live in various types of congregate care settings. This clinical report describes these settings and the care and services that are provided in them. The report also discusses reasons families choose out-of-home placement for their children, barriers to placement, and potential effects of this decision on family members. We examine the pediatrician's role in caring for children with severe intellectual and developmental disabilities and complex medical problems in the context of responding to parental inquiries about out-of-home placement and understanding factors affecting these types of decisions. Common medical problems and care issues for children residing outside the family home are reviewed. Variations in state and federal regulations, challenges in understanding local systems, and access to services are also discussed. *Pediatrics* 2014;134:836–846

INTRODUCTION

Most children and adolescents with developmental disabilities and chronic health conditions live and thrive at home with their families. However, some of them reside outside their family homes. They usually live in congregate care settings in which 4 or more people receive care for a variety of medical, psychiatric, behavioral, and developmental issues. In the past 35 years, the number of children and adolescents living in residential settings has decreased significantly. In 1977, 36% of residents in state facilities were between 0 and 21 years of age. This total does not include children and youth in residential facilities operated by other entities, such as private corporations and religious orders. There has been a significant decrease in the number of residents living in congregate care settings since that time. However, in 2010, 4% of those living in congregate care were between 0 and 21 years of age; approximately one-third of these subjects ($n = 7926$) were younger than 14 years of age.¹ The shift from people with disabilities living in care centers to community living was accelerated by the Olmstead Act of 1999 (http://www.ada.gov/olmstead/olmstead_about.htm), which stated that unjustified segregation of persons with disabilities violates Title II

of the Americans with Disabilities Act. Furthermore, the Olmstead Act mandated that persons with disabilities be provided appropriate and reasonable accommodations for community-based services. Within that context, 1 goal of the Healthy People 2010 program was to “reduce to zero the number of children aged 17 and younger living in congregate care facilities.” The revised goal of Healthy People 2020 is more realistic, aiming to “reduce the number of children and youth aged 21 years and under with disabilities living in congregate care residences” by 10% or from nearly 29 000 children in 2009 to 26 000 children in the next decade.² In 2000, the Centers for Medicare & Medicaid Services reported that there were 4886 children with special health care needs in the United States residing in skilled nursing facilities (SNFs), of whom 1222 had intellectual and developmental disabilities (IDDs).³ Intellectual disability refers to a group of conditions in which there is limited cognitive capacity, significantly reduced adaptive skills, and onset before 18 years of age. Developmental disability is a severe and chronic disability that may affect cognitive and/or physical functioning and has an onset before 22 years of age.⁴ It has been postulated that placement of children and youth (referring to adolescents) with IDDs into SNFs occurs when families are not able to obtain adequate community-based care and support. However, the reasons for placement of children in various types of residential facilities are complex and multifaceted.⁵

In 2005, the Council on Children With Disabilities of the American Academy of Pediatrics (AAP) endorsed the goals of Healthy People 2010, supporting the importance of permanency planning as a means to care for children with special health care needs in the family home.⁶ In response to a published editorial contesting the notion that no

children should be placed in congregate settings,⁷ the Council on Children With Disabilities responded by indicating that, although the AAP endorsed Healthy People 2010, the council did not endorse the specific goal of eliminating congregate care. The council called on the AAP to develop a policy regarding the role of congregate care for children with special health care needs.⁸

The goal of the present report was to review the subject of pediatric congregate care, including the characteristics of children and youth who may be admitted to congregate care centers, definitions of residential placement options, typical reasons for placement, and suggestions for pediatricians who work with children and youth whose families may consider out-of-home placement. This report focused on young people who generally are nonverbal, nonambulatory, and dependent for most or all activities of daily living. Most of these young people have severe to profound intellectual disability, and some have no ability to interact with their environment. Some of the children and adolescents who reside in these settings for respite services or postoperative or rehabilitation care may have less severe presentations or may present with complex and chronic medical conditions, making them totally dependent on others for daily care.

CHILDREN AND YOUTH WITH IDD AND/OR SPECIAL HEALTH CARE NEEDS

Much has been written and acknowledged about the benefits of providing home- and community-based supports for children, adolescents, and adults with a wide range of disabilities and special health care needs.^{9,10} As a result, changes in public and professional awareness, values, policies, funding sources, and programmatic supports have occurred. With these changes, the

vast majority of children and adolescents who require assistance with all or most daily living skills and ongoing skilled nursing care live with their parents.^{1,11} However, children and youth with significant disabilities and special health care needs may have multisystem medical problems that often worsen over time. Children may require care for neurologic, pulmonary, orthopedic, gastrointestinal, endocrine, metabolic, and other medical problems.¹² Although there are home health care agencies and other community-based supports for families, there is substantial variability of resources depending on jurisdiction, funding, diagnosis, and other factors. In addition, not all families have the housing resources or personal capacity to care for children with special needs.

In 2010, approximately one-third of children, adolescents, and adults with IDDs nationwide were on waiting lists for a variety of community-based services and supports.¹¹ At any time, there are more families waiting for services for their children who have technological needs than there are persons available to provide these services, and the necessary funding is not consistent or guaranteed, leaving families to care for their children without professional support. Some children currently residing at home receive more technically demanding care than is possible in many SNFs, including ventilation and intravenous nutrition, placing substantial responsibilities and stresses on families and home life.¹³ The decision to provide this type of care at home may be a choice or a necessity, given some of the financial, resource, and policy constraints.

TYPE OF RESIDENTIAL FACILITIES

There is no consistent definition for the different types of congregate care facilities. The definitions vary state by state, and the term “nursing home”

does not have a formal and generally accepted definition. Nursing homes vary in types of services provided, with “skilled” generally being used to indicate a higher level of nursing care. However, this distinction is not universal, and statistics provided do not clearly make that differentiation. SNFs and intermediate care facilities are places where people live; therefore, these subjects are usually referred to as “residents” rather than patients. Although residents may leave, such as for a visit to their family home, there usually is not an anticipation of a “discharge date.” This type of arrangement differentiates these facilities from transitional settings, residential schools, respite centers, rehabilitation hospitals, and other settings where children may stay for specified periods of time while receiving care related to their disabilities or their medical needs.

SNFs

SNFs, commonly referred to as nursing homes, care for individuals who require 24-hour skilled nursing procedures on a daily basis, regardless of specific diagnosis or etiology, for their medical problems. Pediatric SNFs care for children, youth, and some adults with special health care needs, most of whom also have IDD. Some facilities require residents to have severe to profound intellectual disability for admission. Services provided include ongoing nonoral feeding (eg, gastrostomy or jejunostomy tube feedings), medication administration, suctioning, and skilled assessments. Not every SNF provides the full gamut of technically advanced nursing care, such as tracheostomy care, mechanical ventilator support, intravenous fluid or nutrition, or dialysis. The medical complexity of children admitted to SNFs has increased over the years. In many SNFs, direct patient care is primarily provided by certified nursing assistants

under the direction of registered, licensed practical, or vocational nurses. Physicians make regular rounds, the frequency of which varies between states and even between facilities within the same state; physicians generally are not present on a daily basis. Many facilities also provide short-term respite care, either on a planned or an emergency basis.

The provision of physical, occupational, speech, and behavioral therapies is variable. Specific standards for environmental conditions, staffing levels, and physician certification for facilities caring for children do not exist at a federal level, although standards do exist for SNFs in general. In some states, children can only be admitted to pediatric facilities; in others, they may be admitted to general facilities with or without specific waivers.

Intermediate Care Facilities

Intermediate care facilities are residential facilities that provide daily care for subjects who require care and supervision but who do not require 24-hour-per-day skilled nursing. These services include assistance with activities of daily living, such as feeding, incontinence care, dressing and bathing, medication administration, and safety supervision. They usually do not provide parenteral medication or nonoral feeding.

Acute Care or Specialty Hospitals Providing Long-term Care

Provision of long-term care in this type of setting is a relatively new concept. A physician provides daily assessment and care for patients who require a hospital level of treatment on a long-term basis. This care may include mechanical ventilator management with frequent adjustments, frequent modifications to daily medication regimens, parenteral fluids, and medications, dialysis, complex wound care, and other

medically complex interventions to patients who are not expected to improve in the short-term.

Transitional Facilities

Transitional services are sometimes located within hospital settings and SNFs, although these settings may also be freestanding and located within residential buildings. They primarily provide a transition for patients with skilled care needs who are being discharged from the hospital before returning home. For example, care may be provided to a child with a new tracheostomy while training the family in its use and developing the plan for home care. These facilities also may provide care for children and adolescents with multiple medical needs on a respite or temporary basis or after a change in medical condition, such as postoperative orthopedic surgery care. There is not a consistent definition or licensing for transitional facilities. Although, implicitly, patients are cared for in these settings for relatively short periods of time, the length of placement may vary.

Rehabilitation Hospitals

Rehabilitation hospitals are not congregate care facilities; they provide short-term hospital care with nursing, medication management, and intense rehabilitative therapies. Some SNFs for adults use the term “rehabilitation center,” and some skilled care facilities for adults provide what is termed “subacute rehabilitation,” which implies treatment intended to improve function but at a level less intense than that provided in a rehabilitation hospital. It is unusual for this type of facility to be available for children.

Residential Schools

Some children and adolescents are cared for in residential schools that provide expertise and educational curricula for individuals with specific

health conditions or disabilities. Most of these settings are for children and youth with long-term behavioral or psychiatric problems, although some exclusively serve children with physical or developmental disabilities. The level of nursing and medical care provided within these programs varies. These settings do not provide the same level of care provided in SNFs. The children usually return to their family home during school vacations. These schools may be private or public programs.

Medical Group Homes

In some states, medical group homes have replaced other forms of technologically advanced residential facilities. These homes have providers who typically care for relatively small numbers of patients in adapted single-family homes within residential neighborhoods. Medical group homes may provide nursing care at the level of the SNF.

All of these types of facilities must follow state and/or federal regulations. Skilled care facilities must comply with federal regulations.¹⁴ However, regulations for level of care, environmental safety, staff ratios, and types of residents served, as well as payment sources, vary state by state.¹⁵ Admission is regulated and cannot occur simply by parental or physician request. Specific admission criteria and processes for admission vary by state. In general, individuals younger than 22 years are not able to be placed in adult SNFs, and adults are not admitted to pediatric SNFs. However, there are situations in which subjects obtain waivers to allow for exceptions to these policies. Many states also now allow children to be present in adult SNFs, using “intergenerational models.”

TRANSITIONS TO ADULthood IN CONGREGATE CARE SETTINGS

As young people with significant IDD and special health care needs reach

adulthood, many remain in pediatric facilities because of insufficient community resources to address issues specific to their disabilities and health problems, including insufficient expertise of medical and nursing staff in caring for adults with IDDs in SNFs. In addition, there may be regulations prohibiting the placement of subjects with IDDs in SNFs for adults who are medically fragile but without these types of disabilities. This lack of adequate care options often creates extremely difficult situations for young adults with profound IDDs who have been in residential placement since early childhood and are now over age for the licensed facility where they have always received care. Although some patients remain in the pediatric SNF, the medical and nursing staff may not have experience in the recognition and management of adult medical conditions (e.g., ischemic heart disease). In addition, as adults with IDDs age, many develop special health care needs that may not be adequately met in nonskilled care facilities or at home with aging parents.

CHARACTERISTICS OF CHILDREN WHO LIVE OUTSIDE THE FAMILY HOME

Decades ago, most children referred to residential placement had intellectual or developmental disabilities; some did not have significant medical problems.^{1,2} Certain medical interventions, such as use of feeding tubes and positive-pressure ventilation, were not commonly used in long-term care facilities, with the exception of respiratory care for children with polio. Many families also were encouraged to place their infants with Down syndrome into institutional settings. With the dramatic changes in living situations and community supports for subjects with disabilities over the past 40 years, it would be extremely

difficult to place an infant with Down syndrome who did not have associated chronic complex conditions into an institutional setting today. Home care waivers that allow Medicaid funding for long-term nursing care provided at home, including for families who might not otherwise be financially eligible for Medicaid (e.g., Katie Beckett waivers), began at approximately the same time. The idea, and then the expectation, that long-term sophisticated medical, rehabilitative, and technological care would be provided for children with complicated disabilities co-occurred with support for home care, mandatory eligibility for special education, and the recognition that families of children with developmental disabilities thrived when family members remained together.

The Developmental Disabilities Assistance Bill of Rights Act, section 102,¹⁶ defines developmental disability as a severe, chronic disability that is the result of mental and/or physical impairments, occurs before 22 years of age, is chronic in nature, and results in significant limitations in at least 3 major areas of functioning. Children from birth through age 9 years do not require 3 or more major areas of limitation in the presence of significant developmental delays or specific congenital or acquired conditions, if there is a high likelihood of meeting all criteria later in life if their needs are not addressed. These limitations result in the need for a number of different services and supports for children, youth, and adults.¹⁷ Importantly, most people with developmental disabilities do not have medically complex conditions or chronic illness. There is variability in how states define disability for different types of services, as well as how services are provided to children. Medical diagnoses pertaining to disability generally do not

correspond to educational definitions of disability.¹⁸ Children and adolescents who are medically fragile and/or technology dependent are supported by government, educational, and fiscal programs that do not apply to adults, leading to a significant step-down in services and available supports when reaching adulthood.

Many children and youth who receive skilled care have problems that were acquired or are later-presenting medical conditions, such as acquired brain injury, spinal cord injuries, leukodystrophies, neuromuscular conditions, or catastrophic complications of other illnesses. Although many young individuals in skilled care facilities have severe to profound IDD and complicated medical conditions regardless of etiology, there are some children who require significant medical and technological support in the context of normal or more mildly affected cognitive skills: for example, those with neuromuscular disorders who require assisted ventilation or children and adolescents with long-term need for parenteral nutrition. Their needs for social support, education, recreation, and future planning are different from those of children with severe to profound intellectual disability. The needs of children and adolescents with life-limiting disorders (eg, leukodystrophies) or children whose parents have decided against life-prolonging treatment are also different from those of children with profound disabilities who are expected to live into adulthood.

DIFFERENCES BETWEEN HOME CARE AND RESIDENTIAL CARE

Children and adolescents in congregate care settings are cared for differently than when they are at home. The most obvious difference is that they do not usually have daily contact with parents and siblings, and their care is provided

by different people throughout the day. Families visit their children at variable frequency. Unfortunately, some children have little contact with their families. There also are greater risks of infectious diseases when individuals are in congregate care settings, despite requirements for universal precautions and immunizations.

The care of children and youth in residential settings is driven by physician orders and nursing protocols and may be more regimented than home care (eg, timing of feeding, bathing, and medication administration). Licensed personnel are required to report specific changes and to follow medical orders and facility protocols, whereas parents are free to use their own judgment. Nursing homes may have contractual or regulatory limits on what pharmacies or suppliers they can use; these restrictions may limit access to certain medications, formulas, and types of equipment. In some cases, particularly when there are concerns about the care a family is providing, the protocol-driven nature of congregate care may benefit the child. For example, Henderson et al¹⁹ found that children in residential care who received nonoral feedings demonstrated improved growth compared with children in home care, likely reflective of adherence to specific orders in residential facilities.

Children in residential care retain their rights to a free appropriate public education in the least restrictive setting, and some continue to participate in public schools. Therapy, educational, and recreational services frequently are provided within the facility. Children and adolescents in the community may have providers come into their home, or they may go out to different appointments. There may be fewer environmental barriers in a residential setting, access to multiple caregivers and equipment for lift-

ing, and protocols for care. However, although children and youth in SNFs might have access to technically easier care, round-the-clock caregivers, and an accessible environment that may facilitate recreation and community access, they have extremely limited interaction with typically developing peers. This limitation may be viewed as negative, neutral, or positive, depending on the particular family and child.

REASONS FOR PLACEMENT AND DECISION-MAKING

There have been a number of reports about the reasons for placement of a child, adolescent, or adult family member into a residential setting as well as the effects of that decision on other family members. Factors that affect placement decisions include issues related to the child or youth, family and parental attitudes, cultural practices, influence of the social environment, and the availability (or lack) of external assistance. Some individuals require more care than can be provided in most homes by most families,⁷ although it is clear that some families are able to do more than others for a variety of reasons. Families may not be able to adequately care for their child alone in the context of insufficient community resources, such as a large youth with a high spinal cord injury who is ventilator dependent and requires 2 people to turn him. In other situations, families lack the capability to organize, supervise, and manage a home care staff and may not be able to learn the assessment and technical skills to provide safe care. These decisions are difficult for families, and pediatricians may also be challenged when they believe that a loving family might not be the best provider of care for their own child. Llewellyn et al²⁰ found that parents, as a group, reported their desire to care for their child at home. Despite this

finding, decisions to place a child into a congregate care setting often were made for reasons that the parents considered to be important for the “survival” of the family as a whole.

Perceptions of social challenges also have been found to affect decisions for out-of-home placement in certain situations. In 1 study, parents who expect that their child with disabilities might be stigmatized in the community were found to be more apt to place their child in a residential setting.⁵ Similarly, Hanneman and Blacher²¹ found that the more “normative” the child’s appearance, the less likely families considered residential placement. Conversely, in this report, mothers of higher socioeconomic status and those with more children were more likely to consider out-of-home placement. Stress on the caregiver affected the consideration of placement as well as whether placement actually occurred. Interestingly, support resources and quality of life did not influence placement in this particular study. However, others have found that lack of adequate community-based disability or family support services to meet their particular needs was associated with out-of-home placement.²²

The importance of the well-being of families with children with disabilities has been explored by a number of researchers.^{23,24} Families have been found to make decisions regarding placement that are in the interest of maintaining the highest level of functioning of all family members.²⁵ However, not all families balance the demands of caring for their child with a disability similarly, as the context of other family needs may differ.²⁶ Hostyn and Maes¹⁰ evaluated families who placed their children in residential settings and divided them into 4 groups. Some families, whose children had multiple disabilities, health problems, and complex needs, tended to choose

placement so that the child could lead a comfortable life, with intensive medical and therapeutic supports. These families were also often noted to have difficulty balancing care for the child with disabilities with their other family and work demands. The authors also described families who had children with a developmental disability coupled with significant behavioral problems. These families tended to choose placement because they were not able to handle a child’s behavior, felt guilty and powerless, and were often socially isolated. Some of them also had concerns about the effects of negative behaviors on their other children. In general, children with these characteristics are not appropriate candidates for SNFs because they do not require skilled nursing procedures and they may be independent in activities of daily living. A third type of family was one in which 1 or both parents had physical or mental health problems or an intellectual disability. They also tended to have fewer educational opportunities, social supports, and available resources and were more likely to be unemployed or underemployed. The decision for out-of-home placement in these cases was found to be based on the parents’ feelings of inadequacy to care for their child. A fourth type of family was one in which the primary caregivers were divorced. Although both parents may be much involved in their child’s life, they perceived little support from others. In all groups, parental concern for the well-being of family members other than the child with disabilities was noted, and parents also voiced the belief that residential placement would better support their child with disabilities.

Parents remain the guardians and decision-makers for their children in out-of-home placement. Parents do not “sign away” their parental rights in these situations. Although parents are

the legal decision-makers, there may be limits on the choices parents can make regarding certain types of care for their children based on regulations or facility policy. People who are unable to make their own decisions at the age of majority must have guardians; usually, parents seek guardianship in this situation. Unfortunately, some parents abandon their children by not participating in decision-making and being unavailable for consent. In these cases, the facility must work with state child welfare agencies or, for individuals over the age of majority, with adult protective services or other agencies. There are some families who fulfill the responsibility for consent and decision-making although they are not involved in their children’s lives and do not visit them. Some children who are wards of state child welfare agencies also may be admitted to residential care, such as in situations in which the disability is the direct result of child abuse.

EFFECTS OF PLACEMENT

Baker and Blacher²⁷ evaluated the effects on the family of the placement of a family member with IDD into residential care. The vast majority of families reported that the placement had advantages for all involved. However, although parents of children younger than 15 years visited more frequently, they also reported the highest stress as well as the lowest marital adjustment and advantage to placement. Another study found no significant negative effect on adolescent siblings when a child with an intellectual disability resided outside the family home. The child with intellectual disability also continued to have an influence on family functioning, regardless of the place of residence.²⁵ Hostyn and Maes¹⁰ found that parents generally did not regret their decision to place their child into a residential setting.

Despite the benefits to family life that some have reported after placement in a residential setting, the decision for placement is extremely difficult for families to make.²² The family quality of life before and after placement also has been explored.²⁸ Overall, there were positive changes in the areas of emotions, freedom, and family relationships, although most parents reported continuing guilt and worry.

DURATION OF PLACEMENT

Because parents or guardians retain their parental rights, they may also terminate the placement and take their child home. This action sometimes occurs because parents regret their decision. It may also occur after a change in family circumstance, such as improved financial situation, change in marital status, or ability to access more community supports. In addition, it can occur because of changes or improvement in the child's condition (eg, tracheostomy care no longer needed).

When a child or youth returns to the family home, it is crucial to provide careful discharge planning that includes teaching parents or guardians and determining that they are ready to provide needed care. Important considerations for providing comprehensive home care for medically complex children and adolescents are necessary, as outlined in the previously published policy statement.²⁹ In addition to family training, arrangements need to be made for appropriate nursing services, home modifications, equipment, and transition to a new school program and therapy services.

WHO PROVIDES MEDICAL CARE FOR CHILDREN AND ADOLESCENTS IN RESIDENTIAL CARE?

There are federal regulations regarding the frequency of medical examinations in SNFs,³⁰ although there are no standards for medical directorships

or consultancies in these settings or for intermediate care facilities providing care for people with developmental disabilities. Medical directors can be pediatricians, neurologists, family physicians, or other medical specialists. Some facilities are part of a chain; there may be a single physician or a team of physicians with responsibilities for all the facilities. Some children and adolescents might continue to obtain routine or specialized medical care from their providers before placement. Some facilities have consulting arrangements with other specialists (eg, regular orthopedic, pulmonary, neurology, or rehabilitation medicine clinics on site), and others do not. Some may have arrangements with local acute care or specialty hospitals for inpatient care for children.

It is important for physicians acting as medical directors, primary care physicians, and consultants for children in residential placement to be familiar with their patients' specific medical conditions, which can include extremely rare disorders. They should also be familiar with the frequent complications of severe disability, including progressive respiratory insufficiency, severe musculoskeletal problems, complex seizure disorders, the requirement for tube feeding, and other gastrointestinal disorders. Physicians who act as medical directors should also understand their responsibilities as they relate to policies, procedures, and compliance with local laws, regulations, and regulatory agencies. They should understand internal and external administrative structure and responsibilities, which includes understanding of policy development with regard to safety, infection control, awareness of abuse/neglect by families or employees, reporting responsibilities, consent for treatment requirements, and other issues. Knowledge

and familiarity with issues related to palliative care and end-of-life decision-making are also an integral part of physician responsibilities.¹²

FINANCIAL SUPPORT FOR RESIDENTIAL PLACEMENT

Federal and state funds may be available to support children with severe disabilities and special health care needs to remain at home.³¹ However, it has also been noted that families of children with disabilities have disproportionate out-of-pocket expenses for the care of their children compared with the general population despite public and private insurance coverage, with lower-income families experiencing the most financial burden.^{32,33}

There has been a significant increase in federal funding to provide community support for children and youth with IDD and/or special health care needs, with diminished support for institutional settings. Additional funds for community support are sometimes provided by states, counties, and municipalities.³¹ Most children and adolescents residing in out-of-home settings become eligible for Medicaid, which continues to be a major supporter of care in SNFs across the life span. Although Medicaid coverage for SNFs for those younger than age 21 is optional for states, all states provide this benefit.³⁴ Supplemental Security Income (SSI) of children in SNFs is directed to the SNF for their care, because that is where they live. This policy is often surprising to families who have come to rely on the SSI as part of the family's income. Settings classified as schools or transitional settings do not access the child's SSI. A child with his or her own assets (eg, insurance settlements, inheritances) may not be eligible for public benefits. Private family medical insurance may also be accessed for some services,

such as therapy or care provided outside the SNF, but very few, if any, private insurance policies pay for skilled care placements. The Patient Protection and Affordable Care Act (Pub. L. 111-148) was passed in March 2013, with provisions to improve information accessibility to consumers, emphasize quality assurance and performance improvement, and prevent abuse in nursing homes.³⁵ However, payment for SNFs has not fundamentally changed under this law.³⁶ Because there may be variability in types of funding, each facility has personnel who understand funding sources and billing and should be able to provide that information to families. Educational programming for children and youth in out-of-home settings is generally funded by the school district in which the family lives. If a child attends a residential school because, as part of the individualized education plan process, the local school district has determined that it cannot meet the child's needs in a less restrictive placement, the school district may be responsible for paying for the residential services as well as the educational component. Families, even those with limited resources, may benefit from consultation with a professional skilled in financial planning and estate planning to learn how to maximize public benefits and preserve their ability to provide care and opportunities for all of their children.

Just as funding for home care is precarious in type, amount, and timing, funding for residential care also is limited. Because skilled care facilities must provide care within a strict limit of per diem Medicaid payments, they may decide that the more medically fragile children cannot be cared for adequately for the allowed amount of money. These limitations can lead to situations in which children who need more highly skilled care (eg, ventilation,

dialysis, total parenteral nutrition) will not be accepted for admission and therefore must be cared for at home, with parents providing much of the care with less supervision and fewer physical accommodations and resources than would be possible in an SNF. In essence, the parent provides unpaid skilled care at home, which, supplemented by funded home health care, provides a higher level of care than can be provided in a nursing home. In other situations, children remain in acute care hospitals for long periods of time, sometimes years. Some nursing homes raise money through philanthropy, which can supplement per diem payments for services. Nursing homes may be either for-profit or not-for-profit, and these differences can result in different payment, staffing, and other service provision.

FAMILY SUPPORT IN THE MEDICAL HOME

Families of children with significant IDs and/or special health care needs require support to obtain services, navigate complex systems of care, understand care options, and be supported in making difficult decisions that involve the entire family. The perception that professionals, such as primary care providers, expect families to care for their children at home, coupled with the lack of available support and resources, has been noted to be a source of frustration to families.²⁰ Hostyn and Maes¹⁰ also found that, even with provision of "family support," many families do not feel as if all their needs are being met. Caring for children and youth with complex needs and their families requires ongoing commitment from the primary care physician and the subspecialists who may be providing the majority of the child's medical care. Support from other health professionals, such as social workers,

can provide additional needed assistance to both families and the primary care provider. The support needed will change over time as the child's condition changes and as the family's understanding and relationship with their child evolve and grow. Ideally, the medical home model should provide this type of support; however, there are circumstances in which some parents need more care than can be provided from the medical home and in the community, given the current state of available resources.

CONCLUSIONS

Despite the fact that considerable progress has been made to support children with significant developmental and/or medical problems in the home setting, there continues to be a need for other options of care and living arrangements. The decision to have a child live away from the family home is difficult and complex. Although consideration must be given to providing each child with the best resources and support as possible, the family's needs, stressors, capacity, and relationships must also be considered. The importance of trying to support families to care for the child at home cannot be overstated. However, parents of children with significant special health care needs may, at some point, consider out-of-home placement.

GUIDANCE

1. Pediatricians who care for children and youth with medically complex needs or severe disabilities should, as part of medical home services, be aware and knowledgeable of community supports for these families. This assistance includes familiarity with respite services, programs available to provide nursing or supportive care in the

home, and financial supports for families. State or local agencies with responsibilities for health or developmental disabilities services function as potential sources of information for families and physicians. Agencies such as The Arc (www.thearc.org) and Family Voices (www.familyvoices.org) serve as strong resources for families and medical providers. Many other national resources, such as the National Dissemination Center for Children with Disabilities (www.nichcy.org) and Disability.gov (www.disability.gov), also are helpful.

2. Pediatricians should encourage parents and caregivers to take short breaks and avail themselves of respite services. If a parent appears to be overwhelmed, anxious, or depressed, the pediatrician should express concern and be instrumental in finding support for the parent.
3. Pediatricians should consider consultation with subspecialists who have experience in the longitudinal care of children with special health care needs for assistance with developing home care plans and consideration of long-term care options. These subspecialists might include neurodevelopmental disabilities pediatricians or child neurologists, developmental/behavioral pediatricians, specialists in the child's primary specific disorder (eg, pulmonologists, pediatric physiatrists), or palliative care specialists.
4. Physicians should respect the family's motivation to ensure compassionate, skilled, and medically appropriate care for their child regardless of the setting in which it takes place. A decision to place a child in out-of-home care may be seen as analogous to a family's decision that a child may live with

relatives or attend a boarding school. If a family wishes to consider the option of out-of-home care, the pediatrician should explore the reasons the family is contemplating placement. This type of inquiry also provides an opportunity to revisit the parents' understanding of the child's condition, prognosis, and goals of care and whether the treatment plan is consistent with those goals.

5. Information about care options for children with complex medical problems and IDD is often available through the state health department and/or the state developmental disability agency. The physician can then learn about local facilities and the process for application and provide assistance in this process, as needed. Social work assistance, if available, can assist in accessing information and providing support to families. Personnel from the state agency responsible for screening patients referred for placement should also be available as a resource. They often require an update on the child's medical condition, including up-to-date immunizations, physical examinations, vision and hearing assessments, screening for infectious conditions, a recent psychological assessment, and some laboratory examinations for consideration of admission.
6. The pediatrician should advise the family to visit all the possible facilities being considered, learn about the medical care provided within the facilities, meet the actual direct care providers, and make certain that the facilities meet all the state guidelines. Families of children who are living in the facilities can be excellent sources of information. Office- and hospital-based social workers also may be able to

provide additional support and information to families.

7. The pediatrician should remain available to resume care of the child when he or she is home for visits or returns home on a permanent basis and be available to the medical and nursing staff of the facility when the child is a new resident and the caregivers are not yet familiar with the child's usual condition. Some pediatricians may also continue to provide primary care for the child in a residential setting. It is important that lines of communication be clear; the facility might have policies that restrict orders to the medical director or nursing home medical staff. Direct, concise, person-to-person communication from the primary pediatrician chosen by the parents and medical director of the facility is crucial if shared care is desired by the parent and agreed to by the pediatrician and the medical director of the facility. A portable medical summary, as discussed in the AAP policy statement on transition,³⁷ provides an important mechanism to share medical records. Support for the parents' efforts to ensure safe, compassionate, and adequate care for their child is crucial. The support needed by the family is likely to change over time as the parents' role as direct caregivers diminish and as the child matures and his or her needs also change.
8. Pediatricians may find it useful to educate themselves about local, state, and/or federal issues to support children and youth with complex medical and developmental needs. Pediatricians, individually and through the national and state chapters of the AAP, can endorse policies and legislation that support funding programs for children

with special health care needs and their families. Policies that support children and adolescents who are medically fragile or have disabilities should recognize the diversity in this population, their families, and the communities in which they live. Additional studies are needed to better evaluate the different models of care, health and developmental outcomes of children and youth who have lived or are living in residential care, options available to children who leave or age out of home care, and quality indicators in SNFs. Pediatricians should be involved in the development of policies that guide medical care for children and adolescents in all settings and should advocate for registries of those living in congregate care settings.

9. If parents require assistance exploring issues about guardianship,

health care proxy, or power of attorney as a child reaches the age of majority, pediatricians can refer to The Arc for basic guiding principles (www.thearc.org/page.aspx?pid=2351). Because there is variability based on the state in which a family resides, families may also need to seek the assistance from state disability agencies and legal counsel.

abstract

FREE

Understanding a care coordination framework, its functions, and its effects on children and families is critical for patients and families themselves, as well as for pediatricians, pediatric medical subspecialists/surgical specialists, and anyone providing services to children and families. Care coordination is an essential element of a transformed American health care delivery system that emphasizes optimal quality and cost outcomes, addresses family-centered care, and calls for partnership across various settings and communities. High-quality, cost-effective health care requires that the delivery system include elements for the provision of services supporting the coordination of care across settings and professionals. This requirement of supporting coordination of care is generally true for health systems providing care for all children and youth but especially for those with special health care needs. At the foundation of an efficient and effective system of care delivery is the patient-/family-centered medical home. From its inception, the medical home has had care coordination as a core element. In general, optimal outcomes for children and youth, especially those with special health care needs, require interfacing among multiple care systems and individuals, including the following: medical, social, and behavioral professionals; the educational system; payers; medical equipment providers; home care agencies; advocacy groups; needed supportive therapies/services; and families. Coordination of care across settings permits an integration of services that is centered on the comprehensive needs of the patient and family, leading to decreased health care costs, reduction in fragmented care, and improvement in the patient/family experience of care. *Pediatrics* 2014;133:e1451–e1460

The medical home is the standard of care for all children and adults.^{1–3} The patient-/family-centered medical home (PFCMH) is well positioned to provide coordinated, compassionate, family-centered health care by forming strong links among the primary care provider team, specialist team, nurses, social workers, educators, hospitals, and other health care facilities where patients access services with their family/caregivers and community providers.⁴

Care coordination is a “cross-cutting system intervention”⁵ that is “the deliberate organization of patient care activities between ≥ 2 participants (including the patient) involved in a patient’s care to facilitate the appropriate delivery of health care services. Organizing care involves the marshalling of personnel and other resources needed to carry out all required patient care activities, and is often managed by the exchange of information among participants responsible for different aspects of care.”⁶ Within the context of a high-performing medical home model focused on addressing family-centered needs, care coordination is paramount in developing and fostering partnerships across various settings and communities.⁷

Successful care coordination takes into consideration the continuum of health, education, early child care, early intervention, nutrition, mental/behavioral/emotional health, community partnerships, and social services (as well as payments for these services) needed to improve the quality of care for all children and youth including those with special health care needs, while acknowledging the importance of language and culture in achieving desired outcomes.⁸ It is to be distinguished from disease or case management, which primarily focuses on patients’ medical issues. Case managers work with and guide services intrinsic to their specific agency, often within the constraints of eligibility criteria. In contrast, care coordinators work with and guide the team process, which includes and is driven by the needs of patients and families for services across the community.⁹ These functions include care planning and building collaboration/partnerships with all medical and nonmedical providers working with a patient/family.¹⁰ Rather than focus-

ing on titles (eg, patient navigator, care coordinator, case manager), it is critical to focus on competencies, job descriptions, and functions in the physician-led team caring for the patient and his or her family in and outside the PFCMH.¹¹

NEW INFORMATION AND POLICY DEVELOPMENTS

The American health care system is being challenged to reduce costs of care while improving quality outcomes. A key component of recent legislative and regulatory efforts to achieve these savings includes the redesign of systems of care, building on robust medical and health care homes for both children and adults.¹² One method of achieving these financial outcomes is the reduction in care fragmentation and inefficiency within and across health systems. Fragmentation of care can be addressed with care coordination: “a patient and family centered, assessment driven, team based activity designed to meet the needs of children and youth while enhancing the caregiving capabilities of families.”¹³ Care coordination has been characterized as the set of activities that occurs in the space between providers, visits, and entities.¹⁴ Ultimately, coordination of care enables the achievement of the “triple aim” (better care, better health, and lower cost), a principal outcome for health system transformation.¹⁵

Although adult and pediatric health care organizations underscore common elements of the medical home (which includes care coordination across systems), there are intrinsic differences in their respective systems.¹⁶ The “Five Ds” that distinguish pediatric from adult medical home models are as follows: developmental trajectory, dependency on adults, differential epidemiology of chronic disease, demographic patterns of poverty

and diversity, and overall dollars spent on children versus adults.¹⁷ Another key differentiation is the inclusion and importance of family input in all aspects of coordinated pediatric care. A recent Institute of Medicine report provides 10 key recommendations for high-quality health care, including 1 emphasizing the integral role of the family: “involve patients and families in decisions regarding health and health care, tailored to fit their preferences.”¹⁸ Thus, it is essential that “family” is included in the “patient”-centered care model.¹⁹ As such, we refer to this model as the “patient/family-centered medical home” (PFCMH).

Payment for care coordination services has had limited success over the past decade. The American Medical Association added codes 99487–99489 to its *Current Procedural Terminology* (CPT) manual for care coordination for patients with complicated, ongoing health issues within a medical home, accountable care organization, or similar model.²⁰ The inception of these codes allows physicians to document and bill for coordinating care between community service agencies, linking patients to resources, supporting the transition of patients from inpatient to other settings, and working to limit so-called preventable readmissions.²¹ Pediatricians need to advocate for recognition of the codes via third-party payers in their respective regions.

The multidisciplinary framework outlined in Fig 1 offers a definition of care coordination and articulates its essential activities and competencies. Pediatric care coordination highlights the role of the patient- and family-centered care and team-based activities designed to meet the needs of children and youth. Care coordination addresses interrelated medical, dental, social, developmental, mental health, educational, and financial needs

PEDIATRIC CARE COORDINATION FRAMEWORK

Care Coordination Definition:

Pediatric care coordination is a patient- and family-centered, assessment-driven, team-based activity designed to meet the needs of children and youth while enhancing the care giving capabilities of families. Care coordination addresses interrelated medical, social, developmental, behavioral, educational and financial needs to achieve optimal health and wellness outcomes.

Defining Characteristics of Care Coordination

- | | |
|--|--|
| 1. Patient and family-centered (PFC) | 3. Promotes self-care skills and independence |
| 2. Proactive, planned, and comprehensive | 4. Emphasizes cross-organizational relationships |

Care Coordination Competencies:

- 1) Develops partnerships
- 2) Proficient communicator
- 3) Uses assessments for intervention
- 4) Facile in care planning skills (PFC)
- 5) Integrates all resource knowledge
- 6) Possesses goal/outcome orientation
- 7) Approach is adaptable and flexible
- 8) Desires continuous learning
- 9) Applies solid team/building skills
- 10) Adept with information technology

Care Coordination Functions:

- 1) Provide separate visits and CC interactions
- 2) Manage continuous communications
- 3) Complete/analyze assessments
- 4) Develop care plans (with family)
- 5) Manage/track tests, referrals, and outcomes
- 6) Coach patient/family skills learning
- 7) Integrate critical care information
- 8) Support/facilitate all care transitions
- 9) Facilitate PFC team meetings
- 10) Use health information technology for CC

Washington, DC: The Commonwealth Fund; 2009.) CC, care coordination.

to achieve optimal health and wellness outcomes.¹³

BENEFITS OF AND EVIDENCE FOR CARE COORDINATION

Simply put, care coordination improves outcomes (eg, health care utilization, family functioning/satisfaction, and finances). In a 2009–2010 National Survey of Children with Special Health Care Needs, 43% of parents reported receiving care coordination, as opposed to 47% in the 2005–2006 iteration of the survey.²² These data, which suggest a decrease in receipt of care coordination services over time, warrant further examination. Data analyses from the 2005–2006 National

Survey of Children with Special Health Care Needs revealed positive associations between care coordination, family-provider relations, and family/child outcomes. Specifically, the provision of care coordination was positively associated with patient- and family-reported “receipt of family-centered care,” resulting in “partnerships with professionals, satisfaction with services, ease of getting referrals, lower out of pocket expenses and family financial burden, fewer hours per week spent coordinating care, less impact on parental employment, and fewer school absences and ED visits.”²³

An Illinois study showed that children, youth, and their families had a higher

need for care coordination when communication between health care providers was inadequate.²⁴ Care coordination within primary care pediatric practices is associated with decreased unnecessary office and emergency department (ED) visits, enhanced family satisfaction, and reduced unplanned hospitalizations and ED visits.^{25–27} According to research in New Orleans, families of children and youth with special health care needs in an underserved population experienced enhanced services from nurse care coordinator support.²⁸ In short, fewer unmet needs for services ensue when primary care clinicians are sensitive to the culture and needs of children and youth with special health care needs and their families and incorporate levels of care coordination in care delivery.²⁹ Care coordination conducted as a standard of pediatric practice resulted in increased family satisfaction with the quality of care and also decreased barriers to care.³⁰ Other data have suggested that the PFCMH represents a process of care that may help families manage the daily demands of caring for children with special health care needs through family-centered care, provider-to-provider communication, and provision of care coordination.³¹ A 2011 study in children and youth with special health care needs and their families who received care coordination and individualized care plans via a Medicaid managed care plan study reported improved satisfaction with mental health services and specialized therapies and participants were observed to have a decline in unmet needs, improved satisfaction with specialty care, and improved ratings of child health and family functioning.³²

In a busy medical practice, care coordination fosters improved productivity and efficiency by transferring the mechanics of follow-up care,

referrals, equipment acquisition, letters of medical necessity, patient information, transition of care, and previous authorization to care coordinators rather than physicians. As such, efficiency ensues because physicians can spend less time on nonclinical issues for patients.

IMPLEMENTING CARE COORDINATION IN TRANSFORMED SYSTEMS OF CARE

Quality improvement processes are essential in the transformation to health care delivery models that support care coordination. However, it is critical to recognize that broad implementation of care coordination requires consideration of financing models, workforce development, and the development and implementation of tools supporting the provision of care coordination.³³ The costs of care coordination are not directly reimbursable under many traditional payment models, such as fee-for-service, despite evidence of reductions in health care costs.^{29,34,35} The most recent CPT manual includes codes for care coordination and transition services.²⁰

Health information technology can play a pivotal role in care coordination. Electronic tools can facilitate information sharing among patients/families and their health care teams, and subsequently, health care teams, community partners, and medical and nonmedical providers. For example, previsit summaries, comprehensive health care plans, medical summaries, and personal health records can be shared with, among, and between partners and health care teams caring for patients.⁹

Tracking and monitoring patients via the use of patient registries can support care coordination activities and functions and improve patient safety.⁷ These registries can be incorporated

and supported via electronic health records (EHRs) and other software tools with some adaptation. This technology is still evolving with “meaningful use” criteria of EHRs. Meaningful use is intended to use certified EHR technology to improve quality, safety, efficiency, and accountability; reduce health disparities; engage patients and families as partners; improve care coordination and population and public health; and maintain privacy and security of patient health information.³⁶ Ultimately, it is hoped that meaningful use compliance will result in better clinical outcomes, improved population health outcomes, increased transparency and efficiency, empowered patients/families, and more robust research data on health systems.³⁶ Interoperability of registry functionality and care plans with team members outside of the medical arena, but still in the medical and community “neighborhood” caring for a child, is critical. Care planning includes the use of an “actionable” care plan with assigned tasks/roles, a care plan document, an emergency information form, and/or a medical summary, including past medical history and salient specialist information.⁷ These care plans are developed and implemented with input from members of the team caring for a child, including community partners, educational specialists, primary care providers, dental providers, medical subspecialists and surgical specialists, and, most importantly, the family and patient themselves. Coordinated care plans are used across the continuum of care by including medical, educational, mental health, community, and home care provider input.³⁷ These plans should explicitly state goals with therapeutic (including early intervention) educational/vocational and family interventions to maximize outcomes

for children and youth with special health care needs and to drive successful transitions to adult systems of care. It is essential that care plans are maintained and updated with timely and salient information from all partners to avoid duplication of services and to optimize care for patients. Health care teams are essential to the provision of coordinated care. Teams include, but are not limited to, the patient/family, primary care providers, community partners/agencies, mental health care providers, educational systems, medical subspecialists and surgical specialists, urgent care/ED centers, nurse practitioners, physician assistants, dietitians, child care centers, nursing staff, social workers, therapists, home visitors, and other medical staff. Team building starts with establishing teams of physicians and ancillary staff and working with patients, families, and communities to coach patients/families to optimize their health care and chronic condition management.³⁸

“Relational coordination” is an emerging topic highlighting the fact that coordination is not merely management of the interdependence between tasks but addresses management of the people who are performing tasks. It is defined as “a mutually reinforcing process of interaction between communication and relationships carried out for the purpose of task integration.”³⁹ This concept is particularly relevant to care coordination for children and youth, because care coordination “activities” are as important as the team (eg, families, community partners, physicians, nurses, mental health providers, social workers) performing those activities. Relational coordination values the quality of communication (eg, care plans and meetings) and the quality of relationships between families, patients, providers, and partners.

Internet-based tools can optimize communication between families and providers, provide information, support skills training, allow networking among families, facilitate connections between health care providers and community partners, and elicit patient feedback about care. Comanagement with specialists ensures high quality of care and fosters communication across disciplines for patients with multiple diagnoses.⁴⁰ Also, care coordination augments reciprocity of patient information with transfer across settings (eg, from inpatient to outpatient settings). As health care system redesign evolves, it is critical that practitioners are cognizant of tools and organizations providing resources for care coordination. Several national organizations incorporate standards on care coordination structure, process, and outcomes. Table 1 shows a variety of such organizations and tools.

Given this rapidly changing and innovative landscape, it is imperative to continue education on care coordination, the PFCMH, accountable care organizations (ACOs), and family-centered and -driven health care for practicing physicians, medical students, resident trainees, nurses, nurse practitioners, physician assistants, mental/behavioral health practitioners, and social workers. This workforce training goal can be accomplished through maintenance of certification, continuing medical education, continuing education units, and curricula/competency changes in training. Education of the workforce is critically important, because care coordination functions and family-centered principles must be learned and cultivated. The training of current and future physicians on the value and pragmatic adoption and implementation of care coordination is paramount in ensuring its success in practice. The Accreditation

Council for Graduate Medical Education has selected a care coordination milestone as a key competency in the semiannual assessment of residents in its "Next Accreditation System,"⁴¹ which shows a fundamental commitment to training the next generation of physicians in care coordination. In addition, a Care Coordination Curriculum (funded by the US Maternal and Child Health Bureau) is now available to support the education of care coordination providers. This care coordination curriculum is designed to help fill the void of inadequate training opportunities for care coordinators presently. The target audience for this curriculum includes families and patients as well as physicians, nurses, social workers, and administrative staff. Essentially, it provides a framework for the evolution of team-based patient- and family-centered care coordination. It is currently being used in several state programs and delivery systems working to create care coordination capacity.⁴²

CARE COORDINATION AND ACCOUNTABLE CARE

ACOs are expected to play a key role in achieving the outcomes of the "triple aim."¹⁵ The Medicare Payment Advisory Commission has defined ACOs as "a set of providers associated with a defined population of patients, accountable for the quality and cost of care delivered to that population."⁴³ ACO providers could include a hospital, a group of primary care providers, specialists, and possibly other health professionals who share responsibility for the delivery of the highest quality care at the lowest appropriate cost. Key elements of accountable care include payment reform, performance measurement and accountability, and coordinated continuum of care. In the ACO model, there are incentives to manage health care utilization and

improve quality with shared savings to control cost. The PFCMH model can be enhanced through the ACO model with greater organization, coordination, and integration throughout the care system; yet, defining accountability within and across systems will be a formidable challenge.⁴⁴ One must begin with the premise that, from the perspective of the patient and family, care integration means that seamless and coordinated health care services are delivered across the entire care continuum, irrespective of institutional and departmental boundaries.⁴⁵

Implementing the activities of care coordination, with explicitly articulated roles and responsibilities for all members of the care team, will be foundational to the success of ACOs. The recommendations of a national expert panel tasked with defining the core elements of accountable care for children are presented in Table 2. These elements emphasize the unique needs of children and the role of care coordination in their health care delivery system.

IMPLEMENTATION

Pediatricians are encouraged to provide and partner with the PFCMH team in the office setting to manage patients and work with families and community partners across systems.³⁵ The Care Coordination Measures Atlas, developed by the Agency for Healthcare Research and Quality, provides a list of activities proposed as a means of achieving coordinated care that are organized by domains and perspectives (patient/family, health care professional, system representative) and can be a useful tool in achieving these aims.⁴⁶ There are several organizations that promote medical home and care coordination resources and tools. Table 1 summarizes several organizations, Web sites, and tools available to support those providing

TABLE 2 Summary of Core Principles for Creating Accountable Child Health Outcomes

1. Child health care delivery has the potential to deliver both short- and long-term cost savings.
2. The epidemiology and treatment of chronic conditions in children are different than they are in adults.
3. Families are the drivers of child health.
4. Implementation of life-course approaches is essential for optimal child, adult, and population health outcomes.
5. Children's health care requires a diverse and complex network of nonmedical and medical stakeholders.
6. There is a strong need for well-defined care coordination and integration in children's health care.
7. Children represent a disproportionate segment of the population living in poverty, with large disparities among different subgroups.
8. Child health care quality measures require further development and specialized methods.
9. Payment for child health must incentivize stakeholders to provide elements of accountable care.

Source: unpublished data from SA Londhe, MHA, MA; N Sachedina, MBBS, MBA, MPP; M Mann, MD, MPH; S Wegner, JD, MD; RC Antonelli, MD, MS; March 12, 2012.

services to children and families. As health care reform implementation continues with delivery system changes and ACO evolution, pediatricians can work via their state's American Academy of Pediatrics' chapters, with children's cabinets in respective states/commonwealths, and with other inter-/intraagency state coordinating bodies to ensure that system changes support improved care coordination opportunities for meeting the needs of children and youth. Care coordination activities for implementation include the following:

- establishing formal responsibilities among team members and with the patient and family to comprehensively address patient needs;
- fostering strength-based relationships with families and children while building on existing strengths of patients and their family support systems;
- collaborating with all team members and providers involved in caring for a patient and family, including (but not limited to) medical subspecialists and surgical specialists, nurse practitioners, nurses, mental health care providers, social workers, dietitians, educators, community partners, child care centers, home visitors, and family networks;
- communicating across all systems (medical and nonmedical) involved in a child's care while adhering to Health Insurance Portability and Accountability Act rules and Family Educational Rights and Privacy Act regulations and consent driven by families and patients;
- facilitating transitions between entities (eg, pediatric/adult providers, community partners, hospitals, urgent/emergency care facilities, offices, specialists) and across time;
- assessing needs and establishing clear goals for the patient, family, health care team, and system;
- creating, implementing, and updating a formal written plan of care with family/patient input that is sensitive to their language, values, and culture; examples can be found at the National Center for Medical Home Implementation Web site (
- monitoring, following, and responding to needs and changes over time;
- supporting self-management goals as outlined by the team and patient/family;
- linking and collaborating with community resources and partners, including state Title V Children and Youth with Special Health Care Needs programs (eg, formal meetings, education collaborations, task forces, policy development meetings);
- fostering knowledge about community resources and linking families/patients to those resources commensurate with the needs of the patient, family, and population;
- using quality improvement strategies to facilitate implementation for the medical home team, staff, and partners (eg, EQIPP medical home course, APEX-AAP digital navigator) (see Table 1);
- visiting the National Center for Medical Home Implementation Web site (www.medicalhomeinfo.org)

for assistance and examples of support, resources, and templates in transforming clinical practice into a PFCMH;

- using health information technology and tools to facilitate care coordination^{7–9,40};
- advocating for adequate payment mechanisms for supporting care coordination (using CPT codes)^{20,21,26};
- ensuring ACOs and integrated delivery systems address and promote the integrity of the care coordination model (see Table 2)^{44–46};
- engaging with national organizations dedicated to quality measurement to ensure care coordination metrics and standards are appropriate to advance child health outcomes⁴⁷; and
- supporting efforts to develop practical implementation of care coordination algorithms in practice, practice management, and team development.

SUMMARY AND CONCLUSIONS

Care coordination should be a team- and family-driven process that improves family and health care practitioner satisfaction, facilitates children's and youth's access to services, improves health care outcomes, and reduces costs associated with health care fragmentation, which can lead to under- and overutilization of care. It is imperative that well-defined care coordination is integrated into children's health care. Tools for care coordination include health information technology, integrated health care teams, and Internet-based resources. Because of their foundational reliance on PFCMH, ACOs may support the delivery of high-quality, lower-cost care but only if explicit elements of care coordination are included in delivery

system design and training and resources are provided for care coordination.

RECOMMENDATIONS

1. Use and create mechanisms for patients/families to learn the skills they may need to be partners in their own care and in decision-making for optimal care coordination.⁴⁸
2. Ensure that the patient's and family's needs for services and information sharing (eg, care planning) across people, systems, and functions are met via (a) formal assessments, (b) infrastructure (eg, teams), and (c) tracking (eg, registries); this is crucial in operationalizing care coordination.⁴⁶
3. Continually involve the patient/family (eg, families as partners/advisors), build on the strengths of the patient/family, clearly delineate responsibilities of team members, and create careful handoffs when transitioning across settings (eg, between inpatient and outpatient settings and between pediatric and adult care providers or settings).^{46,49–51}
4. Use and develop efficient and accredited health information systems and information technology advances to foster successful transfer of information; to support collaborative communications between patients, families, and the care team; and to facilitate shared decision-making (eg, developing and using care plans).
5. Use care coordination across transitions between entities of the health care system (ie, between and among patient care teams, across settings, between caregivers, and between health care organizations) and with transitions over time (ie, across the

life span, between episodes of care, across trajectory of illnesses).^{49–51}

6. Ensure that comanagement and communication occur among specialists and primary care providers. This care model requires reciprocal and bidirectional communication (ie, secure e-mail, phone call, note, fax), which can be augmented, but not replaced, with health information technology.^{7,37}
7. Ensure ongoing education of elements of care coordination and the medical home for practicing physicians, nurse practitioners, physician assistants, nurses, medical students, resident trainees (across disciplines), mental/behavioral health care practitioners, social workers, and other health care professionals via specific training/curricula, continuing medical education programs, and publications.^{41,42}
8. Understand the landscape of the PFCMH and care coordination as they relate to national organizations and certification/standards, such as ACOs, the National Committee for Quality Assurance, the Patient-Centered Primary Care Collaborative, the National Quality Forum, quality metrics broadly, and health care reform, including financing of care coordination as well as remote collaborative services (eg, phone, e-mail consults with specialists, phone/e-mail encounters with families) that maximize the potential of children, youth, and families.⁴⁷
9. Collaborate with state Title V agencies and Maternal Child Health Block Grant applications ensuring that care coordination is incorporated and addressed and that best practices of care coordination models are emulated.

10. Understand and use new care coordination codes (99487–99489)²⁰ and advocate for payment of these care coordination services by payers.

abstract

FREE

Anthrax is a zoonotic disease caused by *Bacillus anthracis*, which has multiple routes of infection in humans, manifesting in different initial presentations of disease. Because *B anthracis* has the potential to be used as a biological weapon and can rapidly progress to systemic anthrax with high mortality in those who are exposed and untreated, clinical guidance that can be quickly implemented must be in place before any intentional release of the agent. This document provides clinical guidance for the prophylaxis and treatment of neonates, infants, children, adolescents, and young adults up to the age of 21 (referred to as “children”) in the event of a deliberate *B anthracis* release and offers guidance in areas where the unique characteristics of children dictate a different clinical recommendation from adults. *Pediatrics* 2014;133:e1411–e1436

INTRODUCTION

Bacillus anthracis is often placed at or near the top of potential threat agents by biodefense experts.^{1–3} Because of the potential use of *B anthracis* as a biothreat agent, clinical guidance that can be quickly implemented must be made available for review by clinicians before its use in a bioterrorism event, such as the intentional release of aerosolized spores. It is a rod-shaped bacterium present in the environment and may also exist in a spore form that is easy to disperse. It can remain a potential hazard for weeks to years after bioterror dispersal. Anthrax infection in humans can develop after exposure at different anatomic sites and can manifest in different clinical presentations, including cutaneous, inhalation, and gastrointestinal, all of which can disseminate and lead to meningoencephalitis. Another form of anthrax, injection anthrax, has recently been described in drug users and is associated with contaminated heroin use.⁴ This form of anthrax will not be addressed in this report. Most types of anthrax carry a high mortality, including cutaneous infection if local disease of the skin or mucosal surfaces is untreated and progresses to systemic disease.^{2,5,6} Toxins mediate much of the morbidity and mortality associated with *B anthracis*, including hemorrhage, edema, and necrosis.⁷

The potential danger of *B anthracis* as a bioweapon was dramatically illustrated after an accidental release of spores in 1979 from a military microbiology facility in Sverdlovsk, Union of Soviet Socialist Republics, that resulted in at least 77 cases of human anthrax and 68 deaths.⁸ However, none of the cases reported in this incident involved children. *B anthracis* was also used as a bioweapon in 2001, when spores were intentionally distributed through the US postal system. Of

the 22 resulting cases, 18 had confirmed anthrax, 11 of which had inhalation anthrax; 5 of these cases were fatal.⁹ The other 11 cases, both suspected and confirmed, were nonfatal cutaneous anthrax, 1 of which occurred in a 7-month-old infant, whose disease progressed to systemic illness.¹⁰

This document provides clinical guidance for the prophylaxis and treatment of children in the event of an intentional *B anthracis* release and offers guidance in areas in which the unique characteristics of children dictate a different clinical recommendation from that for adults. A comprehensive review of anthrax as it relates to naturally occurring infection is not provided. Rather, the document gives guidance on caring for children after an intentional release of *B anthracis* when public health officials are recommending prompt prophylaxis of individuals thought to be exposed and rapid treatment of individuals with potential anthrax infection. Guidelines for both treatment and prevention in adults have been developed and are not reviewed in this document.¹¹

Children require special considerations for prophylaxis and treatment, because the clinical presentation and progression of disease for cutaneous, inhalation, gastrointestinal, meningoencephalitis, and disseminated anthrax infection may be different from those in adults. For example, children could be at a higher risk of developing disseminated, systemic disease and/or meningoencephalitis after focal infection. It may be more difficult to diagnose the infection in children by clinical signs and symptoms early in the course, because febrile and respiratory illnesses, which may mimic early symptoms of anthrax, are common in children compared with adults. Furthermore, the signs and symptoms for any type of anthrax infection in infants younger than 2 months are not well defined.¹²

In addition, antimicrobial selection and clinical care may be different for chil-

dren. Young children, as well as children, adolescents, and young adults with disabilities, may have difficulty swallowing oral tablets; compliance also may be reduced with poor-tasting suspensions.¹³ The safety and tolerability of some antimicrobial agents when prescribed for children continuously for weeks to months are not well-studied.

Although the provision of antimicrobial agents and vaccine to asymptomatic children for postexposure prophylaxis (PEP) falls under the aegis of public health authorities, local health care providers should be familiar with available resources during a public health emergency to be prepared to treat symptomatic children (ambulatory and hospitalized) who present with focal or systemic infection. In addition, pediatric health care providers will likely receive questions about antimicrobial prophylaxis regimens from families and will be called on to provide reassurance and guidance to families, specifically regarding adverse effects of the prophylactic antimicrobial agents. Pediatricians and others who provide health care to children will be involved in this process as trusted sources of health care information for their patients and families. Clear lines of communication between clinicians and public health practitioners will help families receive consistent messages, improve disease surveillance and adherence to prophylactic antimicrobial regimens, decrease panic among parents and caregivers, and possibly save lives in the midst of a public health emergency.

The American Academy of Pediatrics (AAP) has developed a Pediatric Preparedness Resource Kit¹⁴ to encourage partnerships and joint decision-making between pediatricians and state and/or local health department representatives. This kit includes information and strategies that will help to promote strategic communications and effective messaging in a situation such

as a *B anthracis* release (see www.aap.org/disasters/resourcekit).

Information and guidance that is specific to the identified exposure after a bioterror release in which spores intentionally target civilians will be provided on the Centers for Disease Control and Prevention (CDC) Web site to assist pediatric health care providers with critical decision-making when dealing with patients, families, health care facilities, and local health departments (www.cdc.gov/anthrax).

This guidance reflects a comprehensive review of the literature and the opinions of individual experts from the AAP and the CDC (referred to as the AAP and CDC Pediatric Anthrax Writing Group) at the time of publication, based on the proceedings of a jointly sponsored workshop, held at the CDC Tom Harkin Global Communications Center in Atlanta, Georgia, in November 2012.

Guidance for pediatric anthrax clinical management is provided in Appendices 1 through 8, which are ordered based on severity of disease to offer easy access in the event of a public health emergency.

CLINICAL PRESENTATIONS OF ANTHRAX

B anthracis is an aerobic, gram-positive, encapsulated, spore-forming, nonhemolytic, nonmotile, rod-shaped bacterium. It causes an acute infection called anthrax that can manifest differently according to the route of exposure: cutaneous, inhalation, and gastrointestinal. Each of these forms can progress to systemic disease, which may present clinically with signs of septicemia with the subsequent development of meningoen- cephalitis.¹⁵

Exposure to aerosolized *B anthracis* is likely to result in a predominance of inhalation and cutaneous anthrax cases; however, gastrointestinal cases also may occur. The clinical presentations as discussed herein are primarily from

reports of anthrax in previously healthy adults. Different clinical presentations may occur across the spectrum of pediatric age groups and in special pediatric populations, such as those with underlying comorbidities or disabilities.

Cutaneous Anthrax

Approximately 95% of naturally acquired cases of anthrax are cutaneous. Clinical disease in children appears to be similar to adults, spanning the spectrum from localized to systemic disease.¹⁶ One of the youngest documented cases of cutaneous infection occurred in a 1-month-old infant who was hospitalized with *B anthracis* infection around the mouth, presumed to have been acquired from his mother with cutaneous anthrax.¹⁷

With cutaneous anthrax, after an incubation period of 1 to 12 days, the skin lesion progresses over 2 to 6 days from a pruritic papule or vesicle into a characteristic depressed black eschar surrounded by moderate to severe edema. The lesion is typically painless and can be accompanied by fever, malaise, headache, and painful lymphadenopathy.^{12,18} The mortality rate for cutaneous anthrax is less than 1% if treated with antimicrobial agents but can be as high as 20% if untreated.^{12,16,17,19} Those with symptoms or signs of systemic involvement or with lesions that involve the head, neck, or upper torso or that are large, bullous, multiple, or surrounded by significant edema have higher mortality rates.^{16,19}

Inhalation Anthrax

Inhalation anthrax has the highest case-fatality ratio of the typical forms of the disease. After being inhaled into the lungs, *B anthracis* spores are transported by macrophages and other phagocytic cells to regional lymph nodes, where either en route or on arrival they can germinate into toxin-producing bacteria. The bacteria and

toxins cause systemic anthrax. Spores may germinate as soon as 1 day or may remain dormant for weeks or months before germinating.^{20,21} Depending on the circumstances of exposure, the inhalation form of anthrax may be the most prevalent form of serious, life-threatening disease after an anthrax attack. The incubation period for inhalation anthrax in humans is not well-defined and has ranged from 1 to 43 days, which may reflect delayed germination of inhaled spores or repeated inhalation of spores from the environment after the original exposure event.⁸ Initial nonspecific signs and symptoms may include mild fever, fatigue, myalgia, and cough, and can resemble a viral respiratory illness.²² Occasionally, these prodromal signs and symptoms briefly improve before abrupt deterioration^{7,23,24} to a more fulminant disease characterized by diaphoresis, stridor, dyspnea, hypotension, or acute respiratory distress.^{7,20,23,25} These patients may develop sepsis accompanied by cyanosis, shock, and hemorrhagic pneumonia. Hemorrhagic pleural effusions often develop. Other organ systems, particularly the central nervous system (CNS), also can be affected secondary to bacteremia, a frequent occurrence in children noted with certain bacterial pathogens. The risk of meningoenitis is not well-defined in children, but in adults with systemic disease, it appears to occur in approximately 50% of cases.^{22,25,26}

In the 5 pediatric inhalation anthrax cases reported from 1900 to 2005, nausea, vomiting, headache, dyspnea, or meningeal signs were exhibited, and 3 of the 5 children died.²⁷ With prompt diagnosis, initiation of combination antimicrobial therapy, and modern critical care, the mortality rate observed in adults with inhalation anthrax dropped from more than 90% for the whole 20th century to 45% in the exposures linked to letters contaminated with *B anthracis* spores in 2001,²³ which suggests

that better outcomes are also likely to occur in children. In 2006²⁸ and 2011,²⁹ adults in Pennsylvania and Minnesota, respectively, were successfully treated for naturally acquired inhalation anthrax, demonstrating the effectiveness of modern treatments.

Gastrointestinal Anthrax

Gastrointestinal anthrax can occur after the consumption of food contaminated with *B anthracis* vegetative cells or spores. After an incubation period of 1 to 7 days after ingestion of bacilli or spores, gastrointestinal anthrax presents with signs and symptoms that can include severe abdominal pain and tenderness, nausea, vomiting, hematemesis, anorexia, and fever progressing to more severe systemic illness.^{20,30–32} With antimicrobial treatment, gastrointestinal anthrax exhibits a mortality rate of 40% or less.³¹

A report by Bravata et al²⁷ indicated that the most commonly reported pediatric gastrointestinal anthrax symptoms, in order from most to least common, were fever, abdominal pain, vomiting, diarrhea, and bloody stool.

Gastrointestinal anthrax also can manifest as oropharyngeal anthrax, which starts as a painless mucosal lesion in the oral cavity or oropharynx. Signs of oropharyngeal anthrax may include dysphagia with posterior oropharyngeal necrotic ulcers, unilateral neck swelling, cervical adenopathy, edema, pharyngitis, and fever. Gastrointestinal anthrax can progress to systemic infection.^{20,31}

Meningeal Anthrax

In contrast to bacterial meningitis attributable to organisms, such as pneumococcus, meningococcus, or *Haemophilus influenzae* type b, *B anthracis* causes a hemorrhagic meningoenitis that involves both deep brain parenchymal hemorrhagic lesions as well as infection of the cerebrospinal fluid (CSF) in the subarachnoid space. All forms of

systemic anthrax can progress to meningoen­cephalitis, which, to date, has been nearly always fatal.^{7,27} However, there is limited experience with treatment using currently available intensive care. In a systematic review of pediatric anthrax by Bravata et al,²⁷ meningoen­cephalitis developed in 7 of 22 patients with gastrointestinal anthrax and 1 of 37 patients with cutaneous anthrax; 6 children had primary meningoen­cephalitis with no apparent focus of entry. Only 1 patient survived. In an autopsy series of adult patients from Sverdlovsk, 50% of fatal cases had evidence of meningeal involvement.³³ Signs of meningoen­cephalitis include fever, altered mental status, meningeal signs, and seizures,³⁴ although in the review by Bravata et al,²⁷ pediatric cases of meningoen­cephalitis presented with fever, headache, delirium, seizures, emesis, and diarrhea. Too few cases exist to provide information on differences in the clinical presentation of meningitis between adults and children.

PEP TO PREVENT INFECTION

Studies have demonstrated that spores with the potential to germinate in vitro could be found in the lungs of non-human primates up to 100 days after inhalation exposure.³⁵ However, the potential for long-term spore survival in the environment or subsequent disease is unknown.³⁶ In the setting of a large-scale release of *B anthracis* spores, the public health response will focus on protecting the exposed population with PEP. The CDC Advisory Committee on Immunization Practices and the AAP Committee on Infectious Diseases recommend a combination of antimicrobial prophylaxis for immediate protection during the first 60 days after exposure and immunization for long-term protection after exposure to *B anthracis* spores.^{18,37} Antimicrobial prophylaxis and immunization in spe-

cial pediatric populations, such as those with underlying comorbidities or disabilities, may differ from those provided below.

Antimicrobial PEP

Similar to adults, all children believed to be exposed to aerosolized *B anthracis* spores should receive at least 60 days of antimicrobial prophylaxis (Appendix 1). In response to an anthrax release, local points of dispensing will be identified and coordinated by public health officials, and will receive, and subsequently dispense, an initial 10-day supply of oral ciprofloxacin or doxycycline (or, if pathogens are documented to be susceptible to penicillin, oral amoxicillin, or phenoxymethyl penicillin may be used). Clindamycin and levofloxacin are considered effective alternative antimicrobial agents. Providing antimicrobial prophylaxis to the local population within 48 hours of the initial exposure is the public health goal, with local supplies being supplemented by antimicrobial agents from other regional or national sources. In the early phases of the response, data gathered by federal and state public health officials will better define the exposed population within the 10 days after that particular exposure. To minimize indiscriminate prescribing and use of antimicrobial agents during the early phases of the response to an event, practitioners are advised to seek advice from local public health officials to determine those in need of PEP. Individuals deemed exposed to aerosolized *B anthracis* spores will be notified by local health authorities in partnership with local professional organizations and health care providers to receive the first dose of anthrax vaccine adsorbed (AVA [BioThrax, Emergent BioSolutions, Rockville, MD]), instructions for the second and third AVA doses, and an additional 50-day supply of antimicrobial agents. This 60-day antimicrobial regimen covers the incubation period of

the disease^{8,38} and provides protection until the vaccine confers immunity.

A limited supply of oral suspension formulations of recommended PEP antimicrobial agents will be available, and distribution strategies will be determined by public health authorities at state and local levels. If oral suspensions are not readily available, doxycycline tablets will be provided with clear directions, as recommended by the US Food and Drug Administration (FDA), on how the tablets can be crushed and added to a food or liquid to create a formulation that is more palatable and designed to improve adherence for those who are unable to swallow a tablet.³⁹

Tetracycline-based antimicrobial agents, including doxycycline, may cause permanent tooth discoloration for children younger than 8 years if used for repeated treatment courses. However, doxycycline binds less readily to calcium compared with older tetracyclines, and in some studies, doxycycline was not associated with visible teeth staining in younger children.^{40,41} Although no prospective data exist on staining of teeth in children younger than 8 years taking a 60-day course of doxycycline, the benefits of preventing life-threatening anthrax infection outweigh the potential risks of injury to teeth. Similarly, although no prospective data exist on the risks of cartilage toxicity with ciprofloxacin, particularly for a 60-day course, the benefits of an extended course for prophylaxis in children outweigh the concerns for potential cartilage toxicity. On the basis of availability, either antimicrobial agent may be used and should provide equivalent efficacy, although prospective data after *B anthracis* bioterror exposure in children do not exist.⁴² Some experts believe that if adverse events occurred with an equal incidence between doxycycline and ciprofloxacin, the potential for tooth staining as a sequela may be

less serious than the potential for long-term cartilage injury.

Additional liquid formulations, such as amoxicillin and liquid suspension forms of doxycycline and ciprofloxacin, may be available in this additional 50-day antimicrobial agent supply for infants and young children or children, adolescents, and young adults with disabilities after the initial 10-day prophylaxis supply has been completed and the antimicrobial resistance profile of the *B anthracis* strain has been determined.

Vaccine PEP

AVA contains proteins from a sterile, cell-free, culture fluid grown from a *B anthracis* strain and contains no live or dead bacteria. All exposed adults are expected to receive AVA intramuscularly or subcutaneously at 0, 2, and 4 weeks in addition to a total of 60 days of antimicrobial prophylaxis.¹¹ AVA has been shown to be safe and immunogenic in clinical trials in adults.³⁷ Serious adverse events after AVA administration in adults were infrequent. However, local adverse events, such as pain, erythema, induration, and swelling, were common.³⁷ Most of these local adverse events were not serious, and self-resolved. The vaccine, usually given as a 0.5-mL dose, contains 0.6 mg of aluminum (as aluminum hydroxide). A 0.5-mL dose of diphtheria, tetanus, acellular pertussis (DTaP [pediatric formulation] or Tdap [adolescent/adult formulation]) vaccine may contain up to 0.85 mg of aluminum. Local adverse events may be similar to those described in adults administered AVA and in children administered other vaccines, with similar aluminum hydroxide concentrations.

On the basis of routine and extensive use of similar vaccines in children 6 weeks of age and older, it is anticipated that AVA should demonstrate immunogenicity to *B anthracis* protective antigen necessary to provide protection against symptomatic infection in children

6 weeks and older. The safety profile should be similar to that in adults, commensurate with prevention of life-threatening infection. However, studies of AVA in children younger than 18 years have not been conducted, and the vaccine is not currently approved by the FDA for use in children. Until there are sufficient data to support FDA approval, AVA will be made available for children at the time of an event as an investigational vaccine through an expedited process that will require institutional review board approval, including the use of appropriate consent documents. Information on the process required for use of AVA in children will be available on the CDC Web site at the time of an event (www.cdc.gov/anthrax), as well as through the AAP and the FDA. All exposed children 6 weeks and older should receive 3 doses of AVA at 0, 2, and 4 weeks in addition to 60 days of antimicrobial chemoprophylaxis. The recommended route of vaccine administration in children is subcutaneous, although both subcutaneous and intramuscular injections appear to achieve similar levels of immunogenicity in 60 days. Children younger than 6 weeks should immediately begin antimicrobial prophylaxis but delay starting the vaccine series until they reach 6 weeks of age.

For children, a local adverse event to a previous dose of AVA is not a contraindication to receiving additional doses, although the subsequent dose should be administered at an alternate site. Large local reactions or systemic adverse events should be evaluated before additional doses are administered. Given the short time intervals between the 3 doses recommended for PEP, parental concerns about local adverse events should be addressed prospectively to increase the likelihood of adherence with the full vaccination schedule.

PEP use of AVA is not yet an FDA-approved indication in any population. The doses for each pediatric age group

that balance immunogenicity, safety, and protective efficacy have not yet been determined. Clinical guidance for use of AVA in infants and children is currently based on data from adult AVA clinical trials and expert opinion, although recommendations for pre-event limited investigation of AVA in children are under consideration. The Presidential Commission for the Study of Bioethical Issues recommends that pre-event pediatric research into medical countermeasures, including AVA administration, should pose only a minimal risk to children and should use an age de-escalation process to determine study participation risk.⁴³ This process would look at safety in 18-year-olds and then progressively assess safety and risk at younger ages. Studies that may cause “no more than a minor increase over minimal risk” will require national review under federal regulations. Local institutional review boards should be aware of their role, before a bioterror event, in facilitating the appropriate use of AVA in children during an event. Federal agencies are collaborating on ways to streamline the consent process in a public health emergency. The intent of all providers and federal agencies is to ensure that all children exposed during an event have appropriate access to vaccine.

Special Vaccination Considerations

AVA should not be coadministered routinely with standard childhood vaccines during an anthrax bioterror event. The coadministration of routine vaccines to children in addition to the recommended 3 doses of AVA within 6 weeks of the final AVA immunization could contribute to increased adverse reactions, resulting in a reduction in adherence to full vaccine schedules for both routine vaccines and AVA. In addition, research on the effect of anthrax vaccine on the immunogenicity of routine vaccines has not been performed. Infants and children who are

hospitalized yet still exposed during an anthrax bioterror event should be vaccinated by using the same schedule as outpatients. Given the host immune response normally documented with infection, those with anthrax infection may not require immunization, but systematically collected data on immunity after infection are not available; therefore, these children also should receive all 3 AVA vaccine doses.

Immunization of children exposed to aerosolized *B anthracis* spores with AVA is a priority, above routine immunizations. Although data are not available in children regarding the types and frequency of adverse events after immunization, or whether administering AVA as soon as a few days after the receipt of routine immunizations will lead to an increased frequency of adverse events, the benefits of AVA in children exposed to aerosolized *B anthracis* spores are currently believed to outweigh these risks.

Routine immunizations should resume 4 weeks after the last AVA dose.

INFECTION CONTROL IN THE HOSPITAL AND COMMUNITY

If patients have had recent exposure to aerosolized *B anthracis* spores, the risk of aerosolization of spores from clothing or skin and subsequent inhalation is unknown but not believed to be high.⁴⁴ Public health officials, in collaboration with the CDC, will issue recommendations, which will be available on the CDC Anthrax Web site (www.cdc.gov/anthrax), on how the public should decontaminate clothing and other surfaces after exposure, as well as how to decontaminate dwellings and public places where children may be present, such as schools and child care centers.

Human-to-human transmission of anthrax itself is exceedingly rare and described only in association with exposure to cutaneous lesions.⁴⁵ Trans-

mission through nonintact skin contact with draining lesions is possible; therefore, use Contact Precautions if a large amount of uncontained drainage is present. Cutaneous lesions will no longer contain vegetative bacilli within 24 hours of starting antimicrobial therapy.⁴⁶ Hand washing with soap and water is preferable to use of waterless alcohol-based antiseptics, because alcohol does not have sporicidal activity. Patient care itself does not appear to pose a risk for transmission to health care providers.⁴⁷ Although Standard Precautions for patient care and disposal of blood and potentially contaminated body fluids adequately address contagiousness from vegetative bacilli, the presence of spores in contaminated body fluids, dressings, and patient linens may require additional sanitizing or disposal measures. Incineration or steam sterilization (121°C for 30 minutes) will destroy spores. Advice on infection control measures that address the need for incineration or steam sterilization will be made, specific to an anthrax event, on the CDC Anthrax Web site (www.cdc.gov/anthrax).

Anthrax PEP is not required for health care workers or other patient contacts as a result of exposure to the patient. However, health care workers and other patient contacts might require PEP depending on other exposure risks. A private room is unnecessary, and Standard Precautions should be used for patient care, including patient transport.

MANAGEMENT OF PATIENTS WITH SUSPECTED AND CONFIRMED ANTHRAX

General Diagnostic and Treatment Considerations

Diagnosis

The initial evaluation of patients with any form of anthrax after a biological weapon exposure should be based on careful clinical examination and labo-

ratory testing of sites of presumed infection. A Gram stain is likely to be the only rapid method for identifying *B anthracis* readily available in a clinical laboratory. The organism is characterized as a gram-positive bacillus that forms long chains of vegetative cells with a "jointed bamboo-rod" appearance in culture or short chains of 2 to 4 cells in direct clinical samples. The organism can be isolated from specimen cultures of blood; skin; respiratory secretions; vesicular, pleural, or ascetic fluid; or stool, as well as from CSF (Appendix 7). Given the high rates of meningoenitis in children who have signs and symptoms of systemic anthrax, lumbar puncture should be performed as resources permit, unless clinically contraindicated (such as suspected increased intracranial pressure).²⁷ Gram-positive bacilli with typical morphology found on unspun peripheral blood smears or in vesicular fluid or CSF are highly suggestive of anthrax.¹⁵

Although most clinical laboratories can provide preliminary culture results, they may not be able to perform sophisticated confirmatory tests, such as polymerase chain reaction (PCR) assay on patient specimens (blood, serum, lesion swabs), lethal factor detection analysis, and immunohistochemical staining of tissue, which are available through local or state public health laboratories or the CDC. Public health laboratories in the Laboratory Response Network (www.bt.cdc.gov/Lrn/), a national network of local, state, and federal public health laboratories, can identify *B anthracis* by standard culture methodology in addition to other methods and can perform antibacterial drug susceptibility testing. For current information on the availability and types of traditional confirmatory tests, as well as newly developed molecular tests, that can be performed by public health authorities,

particularly during a biological weapon exposure, visit the CDC Anthrax Web site. (www.cdc.gov/anthrax/labs/labresearch.html).

Treatment

The production of toxins and the frequent occurrence of meningoen­cephalitis, as well as the presence of latent spores, must be taken into account when selecting antimicrobial agents and the duration of treatment of anthrax. Most of the data used to make these recommendations are based on historical information collected before availability of many of the antimicrobial agents discussed, in vitro studies, and limited nonhuman primate studies. Treatment data that are available almost uniformly come from adult patients. For many of the antimicrobial agents discussed herein, limited pharmacokinetic data are available to make dosing recommendations for anthrax, particularly for young infants and neonates. However, systemic anthrax can be a rapidly lethal disease in humans, so in the absence of compelling, well-documented adverse safety data in children, the most effective antimicrobial agents used in the adult population also should be made available for use in children. Children may require larger doses per kilogram of body weight and more frequent dosing for certain antimicrobial agents to achieve a therapeutic exposure equivalent to that documented to be effective for adults. The recommended doses must be sufficient to ensure a therapeutic antimicrobial exposure required for life-threatening infection (ie, doses that achieve adequate exposure in more than 98% of all children treated). Antimicrobial dosing regimens, both empirical and definitive, for all anthrax clinical presentations in children and neonates are provided in Appendix 2 (cutaneous anthrax without systemic illness), Appendix 3 (systemic anthrax to include inhalation and gastrointestinal infection, without

meningitis), Appendix 4 (systemic anthrax to include inhalation and gastrointestinal infection, with meningitis), and Appendix 6 (dosing in preterm and term neonates 32 to 44 weeks' postmenstrual age).

After an exposure to *B anthracis* aerosolized spores, patients treated for any form of anthrax are at risk for late-occurring inhalation anthrax from residual ungerminated spores that may remain in the lungs for several weeks or months after an inhalation event. Depending on the patient's immune status and age, as well as the type of antimicrobial agent used, some patients recovering from severe systemic disease will develop an immune response that would provide protection against germination of any remaining spores. However, if antimicrobial therapy is initiated early in the illness, the immune response may be blunted,⁵⁸ thus requiring continuation of antimicrobial therapy over several weeks to clear organisms as they emerge from the spore form. There is evidence that symptomatic nonhuman primates that are bacteremic with *B anthracis* and treated with antimicrobial agents for at least 10 days develop an immune response and do not develop clinical disease attributable to retained spores that germinate after discontinuation of antimicrobial therapy.⁴⁸ However, no data exist in either adults or children to identify which infected people may develop protective immunity and at what time after clinical infection. No commercially available assay currently exists that can determine adequate immunity to anthrax.

Children with active infection, either cutaneous or systemic, whose original exposure source was aerosolized spores, should complete initial antimicrobial treatment, then transition to oral PEP to prevent relapse from surviving *B anthracis* spores within the lung that may subsequently germinate. The du-

ration of antimicrobial therapy to prevent relapse is not well established. On the basis of incubation times of up to 43 days in humans and 58 days in animals exposed to aerosol challenge, a full 60-day course of an oral antimicrobial agent is recommended to complete treatment and prophylaxis.^{8,38,49} Therefore, once the treatment course for the active infection is completed, patients should continue with antimicrobial prophylaxis so that they receive antimicrobial treatment for a total of 60 days.

Naturally occurring *B anthracis* is very likely to be susceptible to penicillin; although genetic material that codes for the presence of a penicillinase is present, regulation of these genes may be deficient.^{50,51} Most strains are resistant to cephalosporins.⁵² Further, the naturally occurring strains that are penicillin-resistant remain susceptible to amoxicillin/clavulanate. Given the relative safety and tolerability of the penicillin-class agents in children, most pediatric experts prefer these antimicrobial agents for treatment and antimicrobial prophylaxis if pathogens are documented to be susceptible. Other antimicrobial classes, such as fluoroquinolones or tetracyclines, are likely to exhibit poorer tolerance and increased toxicity, especially during prolonged treatment.

A theoretical concern exists that the use of penicillins as single antimicrobial agents could induce β -lactam resistance, especially if the number of organisms present is high, as can occur with systemic disease. In addition, infection with multidrug-resistant *B anthracis*, including bioengineered strains, is a concern.⁵³ Therefore, public health authorities will monitor for the development of penicillin resistance on an ongoing basis even if strains are initially susceptible.

Given the potential severity of the disease, the fluoroquinolone class of

antimicrobial agents and doxycycline (a tetracycline) are acceptable alternatives if amoxicillin and penicillin are not options, either because *B anthracis* susceptibility is unknown to either of these drugs or because there are other contraindications for their use in treatment. Levofloxacin and ciprofloxacin have been prospectively studied in children, with adequate pharmacokinetic data for levofloxacin use in children older than 6 months and for ciprofloxacin use in children older than 1 year, but less robust data are available for younger infants or neonates. Studies have shown a small but statistically significant increase in arthralgia in children but no documented increase in long-term bone or joint toxicity.⁵⁴ Tetracycline-class antimicrobial agents, in general, are not recommended for first-line therapy of acute bacterial infection in children younger than 8 years (with the notable exceptions of rickettsial, *Ehrlichia*, and *Anaplasma* infections) because of deposition of these compounds in teeth and bones. Although prospective, controlled data are not available, limited retrospective data suggest that children who receive up to 5 standard treatment courses of doxycycline are not likely to have clinically detectable tooth staining.^{40,55}

Early diagnosis and initiation of combination antimicrobial therapy is considered essential for treatment of systemic *B anthracis* infection. Although it is always better to definitively identify the pathogen before treatment is administered, the rapid progression of anthrax may not support this approach. Samples for laboratory testing should be collected before treatment. The AAP and CDC Pediatric Anthrax Guidance Writing Group believe that severe systemic infection survival can improve with combination therapy on the basis of theoretical considerations of different mechanisms of antimicro-

bial activity, drug penetration characteristics, synergy with combinations, increased likelihood of effective drug activity in case of single or multidrug resistance, and decreased likelihood of emergence of resistance. Combinations recommended include both a bactericidal antimicrobial agent and a bacterial protein synthesis inhibitor (see the section "Treatment: Considerations for Combination Antimicrobial Therapy for Anthrax" later in this article). Compared with bacteriostatic agents, bactericidal antimicrobial agents are important for killing vegetative forms emerging from spores and are especially effective, in general, in clinical outcomes when used to treat bacterial meningitis.

The high morbidity and mortality observed with anthrax is attributable primarily to 2 exotoxins (lethal toxin and edema toxin) produced by *B anthracis*. Protein synthesis inhibitors, such as clindamycin, may decrease toxin production, as suggested with group A streptococcal toxic shock syndrome,^{56–58} which may provide an added benefit; however, this potential benefit has not been demonstrated in animal infection models or human cases of anthrax. Additional benefits may be provided by immunologic agents (such as immunoglobulin or antitoxin) that bind to the protective antigen of *B anthracis* to prevent attachment to host cells, neutralize toxin activity, or promote clearance of toxin complexes.

For children with overwhelming, severe disease who are not likely to survive, pediatric palliative care teams, if available, may be of value to consult with treating physicians or to provide support to the family and child.

Cutaneous Anthrax

Diagnosis

If cutaneous anthrax is suspected, swabs of vesicular fluid, eschar tissue,

or punch biopsy can be used to establish the diagnosis. Specimens should be submitted for Gram stain and culture. PCR assay and immunohistochemical staining of biopsies may be available through state or local public health laboratories or the CDC. The CDC provides a complete list of recommended specimens, including those listed previously and additionally blood for culture (or lethal toxin testing or antiprotective antigen serology) and swabs from beneath the eschar (www.cdc.gov/anthrax/labs/recommended_specimen.html).

Treatment

Localized or uncomplicated cutaneous anthrax is a less-severe disease. Historically, naturally acquired infection has been successfully treated in 7 to 10 days with a single oral antimicrobial agent, such as either amoxicillin for susceptible strains or ciprofloxacin, before susceptibility testing or for penicillin-resistant strains (Appendix 2). Many patients with uncomplicated cutaneous anthrax can be treated as outpatients. However, hospitalization is necessary for patients with symptoms or signs of systemic involvement, particularly those with lesions of the head or neck that may rapidly progress to include edema that can compromise the airway.

The use of surgical procedures, such as incision, in the treatment of cutaneous anthrax is usually not required, because the lesions do not contain pus. Use of surgical procedures may be associated with poor outcomes.^{59,60} Treatment should focus instead on early initiation of antimicrobial agents and on local wound care. Exceptions to the general surgical contraindication include interventions to relieve airway obstruction or compartment syndrome, particularly for large or circumferential lesions of the extremities.^{61,62}

As a child is started on therapy, cutaneous anthrax can evolve into disease

with systemic involvement, requiring the use of intravenous combination therapy (Appendices 3 and 4). Children who present with cutaneous anthrax during a biological weapon–related event also may have inhaled spores; after treatment, they should receive additional antimicrobial therapy to complete a total of 60 days of therapy.

Inhalation Anthrax

Diagnosis

For suspected inhalation anthrax, a chest radiograph should be performed to assess for a widened mediastinum, pleural effusions, and/or pulmonary infiltrates. In a review of 82 cases of inhalation anthrax, abnormal radiologic findings were reported in all 26 patients for whom chest radiographs were obtained; findings included pleural effusion in 69% of these patients and widened mediastinum in 54%.²⁵ Radiologic findings in children have been reported in only 2 children with inhalation anthrax, but typical findings, such as pleural effusions and widened mediastinum, were reported in both.²⁷ If there is strong suspicion of anthrax on the basis of exposure history and a questionable chest radiograph, a computed tomography (CT) scan of the chest may provide additional information to support the presumptive diagnosis.⁶³ However, during a biological weapon event, access to diagnostic radiology services may become difficult; therefore, assessing risk of anthrax exposure or clinical signs may be used initially to determine suspicion of inhalation anthrax and guide management accordingly.

Extrapolating from adult data, inhalation anthrax can have a biphasic presentation with initial improvement, followed by precipitous hemodynamic deterioration.^{7,24} Because of this potential for sudden decompensation, patients who are hospitalized and treated for suspected anthrax should have

careful hemodynamic monitoring, including continuous pulse oximetry and continuous cardiorespiratory monitoring for at least 24 to 48 hours, even if initial findings are reassuring.

Treatment: General Supportive Care and Ventilator Management

A review of inhalation anthrax cases from 1990 through 2005 showed a significant association between pleural fluid drainage and survival.²⁵ High concentrations of lethal toxin have been detected in pleural fluid and ascites; therefore, prompt and continuous drainage by chest and/or peritoneal tube is critical. Ultrasonography of the chest may be a useful way to detect and monitor pleural fluid. Thoracotomy may be required for loculated or gelatinous effusions.

Patients with anthrax may require mechanical ventilation because of respiratory distress or imminent shock. In addition, some patients with anthrax may require respiratory support for severe edema that may occur with cutaneous lesions involving the head, neck, oropharynx, or thorax. Intubation or tracheostomy may be required to maintain the airway. Although there are significant differences between the pathophysiology of anthrax and respiratory distress syndrome, standard principles of ventilator management apply in both situations. Standard pediatric sepsis guidelines for fluids, vasopressors, blood products, and hemodynamic monitoring should also be followed (Appendix 7).

Treatment: Considerations for Combination Antimicrobial Therapy for Anthrax

The antimicrobial treatment of inhalation anthrax should follow the guidance for severe, systemic anthrax, both for those children for whom a lumbar puncture can be performed and meningitis is unlikely (Appendix 3)

and those in whom meningitis cannot be ruled out (Appendix 4). Patients presenting with signs or symptoms suggestive of pneumonia or systemic anthrax should be started on combination antimicrobial therapy as soon as possible while awaiting results of confirmatory tests. Before recognition of a *B anthracis* biological weapon event, the differential diagnosis for a severe systemic bacterial infection in a child usually warranted broad-spectrum antimicrobial coverage; however, cephalosporin therapy, often used empirically for community-acquired infections, is not active against *B anthracis*. Once the diagnosis of anthrax is confirmed, or in the midst of a biological weapon exposure, individuals presenting with illness consistent with anthrax would warrant therapy targeted more specifically to *B anthracis*. Given the unique drug disposition in preterm and term neonates during the first month of life, specific doses for this age group have been provided in Appendix 6.

Antimicrobial agents must penetrate into appropriate tissue sites, particularly into the CNS for children with systemic disease, especially if meningitis cannot be excluded. Meningitis and hemorrhagic parenchymal brain infection resulting from hematogenous spread must be considered in all children presenting with severe systemic anthrax.

For therapy of severe systemic anthrax in which anthrax meningitis is a consideration, treatment regimens for meningitis that include 2 bactericidal antimicrobial agents and 1 protein-synthesis inhibitor should be followed (Appendix 4). Before susceptibility testing, and for penicillin-resistant strains, ciprofloxacin remains the preferred bactericidal antimicrobial agent, in addition to meropenem. If those antimicrobial agents are not available, levofloxacin or imipenem should be

used. For susceptible strains, penicillin G (intravenous) or ampicillin are recommended, in addition to ciprofloxacin, as first-line antimicrobial agents, avoiding the unnecessary broad-spectrum activity of meropenem. Linezolid is the preferred protein-synthesis inhibitor for CNS infections on the basis of tissue penetration characteristics (Appendix 4). However, if meningitis has been ruled out by CSF examination and/or imaging, treatment may be reduced to a combination of 2, rather than 3, antimicrobial agents with activity against *B anthracis*: 1 with bactericidal activity and 1 protein synthesis inhibitor (Appendix 3). If it is not possible to examine the CSF or perform imaging studies, but the clinical examination 2 to 3 days into therapy suggests that meningitis was not present by a normal neurologic examination, initial triple antimicrobial therapy can be stepped down to dual antimicrobial therapy (Appendix 3).

When meningitis is not a concern, clindamycin should be used as a protein synthesis inhibitor, rather than linezolid, primarily on the basis of concerns for safety. Doxycycline is an alternative protein synthesis inhibitor choice for treatment in all pediatric age groups for non-CNS anthrax. Rifampin is an additional option with the potential to provide synergistic antibacterial activity when used in combination with other agents if the preferred antimicrobial agents are not available or not tolerated.

After completing initial combination therapy for severe disease, all children with systemic illness, excluding meningitis, may switch to oral follow-up therapy (assuming that children can tolerate oral therapy and families are adherent to providing therapy) to complete a 14-day or longer treatment course (as dictated by clinical improvement), followed by prophylaxis,

totaling 60 days (Appendix 5). Although data on the efficacy of oral follow-up therapy after short-course parenteral therapy of systemic anthrax are lacking, the recommended antimicrobial agents all have good oral absorption characteristics and have been used as oral therapy of other infections in children. Children who appear to be well, with no ongoing signs or symptoms of active infection, may be transitioned from parenteral therapy to monotherapy for the remainder of their 14 days of treatment. Those for whom there is some degree of concern about persistent deep infection or who are slower to recover may be transitioned to oral therapy that includes both a bactericidal antimicrobial agent and a protein synthesis inhibitor for the remainder of their 14 days of treatment (Appendix 5). Ciprofloxacin is the preferred antimicrobial agent for penicillin-resistant strains. Doxycycline, clindamycin, and levofloxacin should all provide adequate single-drug therapy. For penicillin-susceptible strains, amoxicillin is preferred therapy, although treating physicians should be aware of theoretical concerns for emergence of penicillin-resistance during monotherapy and be alert to the possibility of clinical deterioration as a result of resistance. In these situations, cultures should be obtained, if possible, to determine whether the organism has become resistant to amoxicillin, and the class of prescribed antimicrobial agent should be changed to those active against penicillin-resistant strains, as noted previously.

Gastrointestinal Anthrax

Diagnosis

When gastrointestinal anthrax is suspected, blood cultures should be performed before starting antimicrobial therapy, and culture and PCR of ascites fluid, stool or rectal swabs, or oropharyngeal lesions, if present, are

recommended. Please see www.cdc.gov/anthrax/labs/recommended_specimen.html for all recommended diagnostic specimens for gastrointestinal anthrax.

Treatment

Antimicrobial therapy should follow the same guidance as that for systemic inhalation anthrax: 3 antimicrobial agents for children with possible or documented associated meningitis (Appendix 4) and 2 for those in whom meningitis can be excluded (Appendix 3).

Anthrax Meningoencephalitis

Diagnosis

Evaluation of CSF in the stable patient can provide laboratory evidence of meningoencephalitis as well as microbiologic confirmation of the etiology. For children too unstable to undergo lumbar puncture, CNS imaging by CT with contrast or magnetic resonance imaging with contrast should be able to document both meningeal enhancement characteristics of infection in addition to identification of hemorrhagic parenchymal lesions characteristic of anthrax meningoencephalitis. If imaging is not possible in the child with altered mental status or seizure activity, then clinical examination findings suggestive of meningitis (such as nuchal rigidity) should be presumed to be caused by meningoencephalitis and treated accordingly. If meningitis cannot be ruled out by laboratory, imaging, or physical examination, the child should be treated as though meningoencephalitis is present.

Treatment

Patients with confirmed or presumptive anthrax meningoencephalitis should be treated with 3 intravenous antimicrobial agents as noted previously in "Treatment: Considerations for Combination Antimicrobial Therapy for

Anthrax.” All antimicrobial agents used should have good CNS penetration, at least 2 should have bactericidal activity, and at least 1 should inhibit protein synthesis (Appendix 4). It is assumed that during a biological weapon event, limited availability of some antimicrobial agents will exist; therefore, many alternative antimicrobial agents also have been listed, some lacking documented evidence of efficacy in CNS infections.

Intravenous ciprofloxacin is recommended as the primary bactericidal antimicrobial agent for meningoen- cephalitis on the basis of efficacy in nonhuman primate infection models and use in anthrax cases since 2001, unless ciprofloxacin use is contra- indicated. Levofloxacin and moxi- floxacin are considered equivalent alternatives to ciprofloxacin, although less experience is available with these antimicrobial agents in children. These fluoroquinolone antimicrobial agents have been shown to have adequate CNS penetration.^{64,65} No re- ports exist to document naturally occurring fluoroquinolone-resistant strains. However, in vitro resistance can be induced, which has implica- tions for bioengineered strains.

An antimicrobial agent from the β -lactam class with activity against *B anthracis* is recommended in combi- nation with fluoroquinolones to treat systemic anthrax cases in which meningitis may be present. If antimi- crobial susceptibilities are unknown or if the *B anthracis* strain is resistant to penicillin, meropenem is the pre- ferred antimicrobial agent, because carbapenems are stable to the β -lactamases of *B anthracis*, and meropenem is approved by the FDA for use in pediatric meningitis; how- ever, meningoen- cephalitis caused by *B anthracis* has not been prospectively studied. If meropenem is not avail- able, imipenem/cilastatin is considered

equivalent in antibacterial activity. How- ever, imipenem/cilastatin is associated with an increased risk of seizures when used in the treatment of menin- gitis, presumably by lowering the sei- zure threshold,^{66,67} and should be used with caution in patients with suspected meningitis. Pharmacokinetic data are available for use in children. Limited data are available for doripenem pharmacokinetics or clinical efficacy in children, but if meropenem and imi- penem are not available, data from experimental animal models of men- ingitis suggest similar efficacy.⁶⁸ If the isolated *B anthracis* strain is suscep- tible to penicillin, penicillin G or ampi- cillin are preferred antimicrobial agents given their long history of use, safety profile, and narrower antimi- crobial spectrum. However, as noted earlier, most strains contain a β -lac- tamase that is usually not associated with clinically relevant resistance but represents a potential for development of resistance to penicillin or ampicillin while on therapy. Emergence of re- sistance to penicillin would require treatment with meropenem or another carbapenem (Appendix 4).

Vancomycin has demonstrated in vitro activity against naturally occurring strains but has limited human clinical treatment data in anthrax. Vancomy- cin is bactericidal, achieves adequate CNS concentrations, has been used extensively in pediatric meningitis, and may be used as an alternative antimicrobial agent if β -lactam anti- microbial agents are not available (Appendix 4).⁶⁹

At least 1 antimicrobial agent that inhibits protein synthesis is recom- mended for inclusion in the antimi- crobial regimen to reduce production of exotoxins. Linezolid is recommended as the first-line protein synthesis in- hibitor. It is recommended over clin- damycin when meningitis is suspected or cannot be excluded, as it is likely

to provide better CNS penetrance, although prospective, controlled data on the treatment of CNS infections with either antimicrobial agent do not ex- ist.^{70–73} Linezolid toxicity must be taken into consideration. Peripheral and optic neuropathy have been re- ported in both adults and children receiving prolonged courses of line- zolid.^{74–76} Myelosuppression is a po- tential adverse effect more commonly seen when linezolid is used for more than 14 days, but it is reversible and can be managed with marrow-stimulating agents.⁷⁷ Linezolid should be used with caution in patients with preexisting myelosuppression. If patients have con- traindications to linezolid use or it is not available, clindamycin is an acceptable alternative. Rifampin, although not a protein synthesis inhibitor, has been widely used for antibacterial synergy with a primary drug and could be used in this capacity if neither linezolid nor clindamycin are available.

Chloramphenicol historically has been used to successfully treat anthrax⁷⁸; it is a protein synthesis inhibitor with excellent CNS penetration. The in- travenous form is not widely available in the United States, and the oral formulation is no longer available. In- travenous chloramphenicol would be an acceptable alternative if linezolid, clindamycin, and rifampin are not available for use. Doxycycline should not be used as first-line therapy if meningitis is suspected because of variable CNS penetration compared with fluoroquinolones and β -lactams, but it may be effective if other pre- ferred antimicrobial agents are not available or are not tolerated.

Duration of initial intravenous combi- nation therapy is determined by meningitis risk and clinical response to treatment. With mortality rates for meningoen- cephalitis approaching 100%, no prospective data exist on which to base recommendations for an effective

treatment duration.⁶⁹ For children with meningoencephalitis or in children for whom meningitis cannot be ruled out, combination therapy is recommended for a minimum of 2 weeks, depending on the severity of disease and presence of brain parenchymal hemorrhagic lesions. Intravenous therapy should continue until the patient is clinically stable, with all clinical signs and symptoms and laboratory and imaging data documenting resolution of inflammation, even if required for 3 to 6 weeks. As with other forms of anthrax secondary to a biological weapon exposure, ongoing oral PEP therapy should continue until antimicrobial therapy has been administered for a total of 60 days.

Use of Corticosteroids

There are limited data to guide use of corticosteroids in anthrax. Clinicians should maintain a high index of suspicion for adrenal failure and perform adrenal hormone replacement therapy with dosing appropriate for stressed patients if adrenal failure is suspected on the basis of history or pressor-refractory hypotension. Although there are no randomized trials of corticosteroid use in human anthrax, adjunctive corticosteroids in anthrax may be considered for management of severe edema or meningoencephalitis. In a systematic review of anthrax meningitis by Sejvar et al,⁶⁹ survival was slightly increased among patients with meningoencephalitis who received steroids compared with those who did not. Several small observational studies of anthrax involving the head and neck appeared to favor their use in this setting. Although corticosteroid doses have not been studied prospectively in anthrax, doses previously used in pediatric bacterial meningitis (dexamethasone 0.6 mg/kg per day, in divided doses every 6 hours for 4 days) should be appropriate.⁷⁹

Antitoxins

Human data from the pre-antimicrobial era suggest that nonhuman anthrax antiserum reduced the mortality rate for cutaneous anthrax and that antiserum might be beneficial in inhalation anthrax. Two antitoxin products are in the Strategic National Stockpile: raxibacumab (a humanized monoclonal antibody) and Anthrax Immune Globulin (AIG [a polyclonal human immunoglobulin]). Raxibacumab is approved by the FDA for use in adults and children for the treatment or prevention of anthrax. On the basis of animal studies, pediatric population pharmacokinetic modeling was performed by the manufacturer, and proposed weight-based doses for children are provided on the package label (www.accessdata.fda.gov/drugsatfda_docs/label/2012/125349s000lbl.pdf). AIG is not currently approved by the FDA and will need to be administered under an Investigational New Drug application or Emergency Use Authorization during a mass exposure event.

Suggested doses of antitoxin preparations for children that reflect current knowledge of the product will accompany raxibacumab and AIG when these products are shipped to points of dispensing located in proximity to the anthrax exposure site. Both products inhibit *B anthracis* protective antigen binding to the anthrax toxin receptors on human cells and subsequent translocation of the 2 primary toxins into cells.⁸⁰

In animal studies, both raxibacumab and AIG have been shown to be effective for treatment of inhalation anthrax when administered without antimicrobial agents.¹ Both have been studied in animals as adjunctive therapy with antimicrobial agents when treatment is delayed and appear to provide additional survival benefit. Both products have been studied in adult volunteers for pharmacokinetics and safety. AIG

has been administered to 3 adults with inhalation anthrax, 1 with gastrointestinal anthrax, and 15 with injection anthrax. Raxibacumab has been used in animal models of inhalation anthrax but has not yet been used to treat human disease. The products appear to be safe and well-tolerated. Headache, sore throat, and nausea were the most commonly reported adverse effects with AIG, and rash occurred in a small number of recipients of raxibacumab. Pretreatment with diphenhydramine is recommended for patients who will be receiving raxibacumab (www.accessdata.fda.gov/drugsatfda_docs/label/2012/125349s000lbl.pdf).

The AAP and CDC recommend the use of antitoxin in addition to systemic antimicrobial agents for all patients with highly suspect (eg, child exposed during a bioterror event, with systemic signs and symptoms compatible with inhalation, gastrointestinal, or meningeal anthrax) or confirmed systemic anthrax. Antimicrobial agents alone can be effective if initiated early in the course of disease. However, given the high mortality rate of systemic anthrax and the apparently low risk of antitoxins, the potential benefits appear to greatly outweigh the risks. Data on the optimal timing are lacking, but most experts favor early administration. During a biological weapon event in which the number of patients with anthrax exceeds available antitoxin and ill patients may overwhelm the health care system, antitoxin should be reserved for patients most likely to benefit from it, including (1) noncritically ill, nonmoribund children with confirmed systemic anthrax in relatively stable clinical condition, and (2) critically ill nonmoribund children who may have progressive disease with dysfunction in 1 or more organ systems. In such an event, antitoxin should be added to combination antimicrobial therapy. Insufficient data are

available to recommend one antitoxin product routinely over the other. During an event, recommendations on dosing will be provided with the antitoxin products.

CONSIDERATIONS FOR BREASTFEEDING INFANTS

Unless breastfeeding mothers have untreated cutaneous lesions on their breasts, mothers should initiate and continue breastfeeding, if able, after exposure to *B anthracis* spores when they are undergoing treatment of disease and when they are receiving vaccine and antimicrobial agents for PEP. Cutaneous lesions are not considered contagious after 24 to 48 hours of effective antimicrobial therapy. Given the various considerations of the potential lethality of anthrax in both the infant and mother, antimicrobial efficacy, infant safety, and the well-known benefits of breastfeeding, the selection of antimicrobial agents and PEP for breastfeeding mothers should not be modified from those for the general adult population. More specific recommendations for compatibility of certain antimicrobial agents and breastfeeding can be found in Appendix 8.

The decision with respect to PEP therapy for breastfeeding mothers should be independent of that for the infant,⁸¹ including the long-term use of fluoroquinolones or doxycycline. The safety of 60 days of infant exposure to maternal antimicrobial agents through human milk is largely unknown but should not in any way affect the need to appropriately treat the mother.⁸² Breastfeeding infants should receive prophylaxis as recommended, regardless of the prophylaxis status of the mother. Additional guidance for pregnant and lactating mothers may be found in a recent review from the CDC by Meaney-Delman and colleagues.⁸³

CONCLUSIONS

The use of *B anthracis* as a biological weapon is considered by the US government to be a potential national security threat. Therefore, the clinical and public health communities must be prepared to dispense prophylactic antimicrobial agents, antitoxin agents, and vaccines¹¹⁵ to prevent disease and treat children who develop infection. To optimally manage children during an anthrax bioterror event, ready access to information from public health officials by health care providers and information communicated back to public health officials from health care providers is critical. Clear recommendations and consistent messaging to the public from both public health officials and health care providers will be extremely important.

Recommendations and key considerations (main points) in a mass *B anthracis* exposure scenario include the following:

Management of Exposed but Asymptomatic Children

1. Within 48 hours of exposure to *B anthracis* spores, public health authorities plan to provide a 10-day course of antimicrobial prophylaxis to the local population likely to have been exposed, contingent on available resources.
2. Within 10 days of exposure, public health authorities plan to further define those who have had a clear and significant exposure and will require an additional 50 days of antimicrobial PEP as well as the 3-dose AVA series under an Investigational New Drug application. For children younger than 6 weeks (who are not candidates for AVA), antimicrobial prophylaxis should begin immediately, but the vaccine series should be delayed until the child reaches 6 weeks of age.

3. A local adverse event to a prior dose of AVA is not a contraindication to receiving additional doses, although the subsequent dose should be administered at an alternate site and closely monitored.
4. Although not strictly contraindicated, AVA should not be coadministered with routine childhood vaccinations during an anthrax event.

Management of Disease

5. Anthrax may occur in different clinical forms, any of which may progress to systemic disease. Treatment will vary by clinical manifestation.
6. Cutaneous anthrax without systemic involvement that occurs in the context of an anthrax bioterror event should be treated with a single oral antimicrobial agent.
7. Inhalation, gastrointestinal, or other systemic disease without meningoencephalitis should be treated with at least 2 intravenous antimicrobial agents: a bactericidal agent and a protein synthesis inhibitor.
8. Systemic disease with possible or confirmed meningoencephalitis should be treated with 3 intravenous antimicrobial agents with adequate CNS penetration, including 2 bactericidal agents and a protein synthesis inhibitor.
9. Antitoxin (either AIG or raxibacumab) is recommended for children with anthrax systemic disease.
10. Corticosteroid adjunctive therapy may be considered in the management of children with severe cerebral edema or meningoencephalitis.
11. Once therapy has been completed for any form of systemic or cutaneous anthrax infection in children involved in an aerosol *B anthracis* dispersal event, appropriate oral antimicrobial agents

should be provided to complete a full 60 days of therapy.

12. Breastfeeding should continue for infants of mothers who require antimicrobial treatment or prophylaxis or anthrax vaccine.

APPENDIX 1 Postexposure Prophylaxis for *B anthracis* (for Children 1 Month of Age and Older)**1. For penicillin-resistant strains or prior to susceptibility testing*****Ciprofloxacin*, 30 mg/kg/day, by mouth (PO), divided every 12 h (not to exceed 500 mg/dose)**

OR

***Doxycycline*,^a <45 kg: 4.4 mg/kg/day, PO, divided every 12 h (not to exceed 100 mg/dose) >45 kg: 100 mg/dose, PO, given every 12 h**

OR

***Clindamycin*,^b 30 mg/kg/day, PO, divided every 8 h (not to exceed 900 mg/dose)**

OR

***Levofloxacin*,^c <50 kg: 16 mg/kg/day, PO, divided every 12 h (not to exceed 250 mg/dose) >50 kg: 500 mg, PO, given every 24 h**

OR

2. For penicillin-susceptible strains^{b,d}***Amoxicillin*, 75 mg/kg/day, PO, divided every 8 h (not to exceed 1 g/dose)**

OR

Penicillin VK*, 50–75 mg/kg/day, PO, divided every 6 to 8 h*Duration of Therapy: 60 days after exposure**

Bold font: preferred antimicrobial agent (when 2 bolded antimicrobial agents are present, both are considered equivalent in overall safety and efficacy).

Normal font: alternative selections are listed in order of preference for therapy for patients who cannot take first-line therapy or if first-line therapy is unavailable.

Doses are provided for children with normal renal and hepatic function. Doses may vary for those with some degree of organ failure.

Italicized font: indicates FDA approval for the indication in the pediatric population.

^a A single 14-day course of doxycycline is not routinely associated with tooth staining, but some degree of staining is likely for a prolonged treatment course of up to 60 days.^b On the basis of in vitro susceptibility data.^c Safety data for levofloxacin in the pediatric population are limited to 14 days for duration therapy.^d Be aware of the possibility of emergence of penicillin-resistance during monotherapy with amoxicillin or penicillin.**APPENDIX 2** Treatment of Cutaneous Anthrax Without Systemic Involvement (for Children 1 Month of Age and Older)**1. For all strains, regardless of penicillin susceptibility or if susceptibility is unknown*****Ciprofloxacin*, 30 mg/kg/day, by mouth (PO), divided every 12 h (not to exceed 500 mg/dose)**

OR

***Doxycycline*,^a <45 kg: 4.4 mg/kg/day, PO, divided every 12 h (not to exceed 100 mg/dose) ≥45 kg: 100 mg/dose, PO, given every 12 h**

OR

***Clindamycin*,^b 30 mg/kg/day, PO, divided every 8 h (not to exceed 600 mg/dose)**

OR

***Levofloxacin* <50 kg: 16 mg/kg/day, PO, divided every 12 h (not to exceed 250 mg/dose) >50 kg: 500 mg, PO, given every 24 h**

OR

2. Alternatives for penicillin-susceptible strains^c***Amoxicillin*, 75 mg/kg/day, PO, divided every 8 h (not to exceed 1 g/dose)**

OR

Penicillin VK*, 50–75 mg/kg/day, PO, divided every 6 to 8 h*Duration of therapy:****For naturally acquired infection: 7–10 days.****For a biological weapon-related event: will require additional prophylaxis for inhaled spores, to complete an antimicrobial course of up to 60 days from onset of illness (see Appendix 1, Postexposure Prophylaxis).**

Bold font: preferred antimicrobial agent.

Normal font: alternative selections are listed in order of preference for therapy for patients who cannot take first-line therapy or if first-line therapy is unavailable.

Doses are provided for children with normal renal and hepatic function. Doses may vary for those with some degree of organ failure.

Italicized font: indicates FDA approval for the indication in the pediatric population.

^a A single 10- to 14-day course of doxycycline is not routinely associated with tooth staining.^b On the basis of in vitro susceptibility data.^c Be aware of the possibility of emergence of penicillin-resistance during monotherapy with amoxicillin or penicillin.

APPENDIX 3 Combination Therapy for Systemic Anthrax When Meningitis Can Be Ruled Out (for Children 1 Month of Age and Older)**1. A bactericidal antimicrobial****a. For all strains, regardless of penicillin susceptibility or if susceptibility is unknown****Ciprofloxacin, 30 mg/kg/day, intravenously (IV), divided every 8 h (not to exceed 400 mg/dose)**

OR

Meropenem, 60 mg/kg/day, IV, divided every 8 h (not to exceed 2 g/dose)

OR

Levofloxacin <50 kg: 20 mg/kg/day, IV, divided every 12 h (not to exceed 250 mg/dose) >50 kg: 500 mg, IV, given every 24 h

OR

Imipenem/cilastatin,^a 100 mg/kg/day, IV, divided every 6 h (not to exceed 1 g/dose)

OR

Vancomycin, 60 mg/kg/day, IV, divided every 8 h (follow serum concentrations)

b. Alternatives for penicillin-susceptible strains**Penicillin G, 400 000 U/kg/day, IV, divided every 4 h (not to exceed 4 MU/dose)**

OR

Ampicillin, 200 mg/kg/day, IV, divided every 6 h (not to exceed 3 g/dose)

PLUS**2. A Protein Synthesis Inhibitor****Clindamycin, 40 mg/kg/day, IV, divided every 8 h (not to exceed 900 mg/dose)**

OR

Linezolid^b (non-CNS infection dose): <12 y old: 30 mg/kg/day, IV, divided every 8 h ≥12 y old: 30 mg/kg/day, IV, divided every 12 h (not to exceed 600 mg/dose)

OR

Doxycycline^c <45 kg: 4.4 mg/kg/day, IV, loading dose (not to exceed 200 mg); ≥45 kg: 200 mg, IV, loading dose then <45 kg: 4.4 mg/kg/day, IV, divided every 12 h (not to exceed 100 mg/dose); ≥45 kg: 100 mg, IV, given every 12 h

OR

Rifampin,^d 20 mg/kg/day, IV, divided every 12 h (not to exceed 300 mg/dose)**Duration of therapy: For 14 days or longer until clinical criteria for stability are met (see text). Will require prophylaxis to complete an antimicrobial course of up to 60 days from onset of illness (see Appendix 1).**

Systemic anthrax includes inhalation anthrax; injection, gastrointestinal, or cutaneous anthrax with systemic involvement, extensive edema, or lesions of the head or neck.

Children with altered mental status, signs of meningeal inflammation, or focal neurologic deficits should be considered to have CNS infection if CSF examination is not possible. A normal CSF may not completely exclude deep brain hemorrhage/abscess. See Appendix 4 for therapy of CNS infection.

Bold font: preferred antimicrobial agent.

Normal font: alternative selections are listed in order of preference for therapy for patients who cannot tolerate first-line therapy or if first-line therapy is unavailable.

Doses are provided for children with normal renal and hepatic function. Doses may vary for those with some degree of organ failure.

^a Increased risk of seizures associated with imipenem/cilastatin therapy.^b Linezolid should be used with caution in patients with thrombocytopenia, as it may exacerbate it. Linezolid use for >14 days carries additional hematopoietic toxicity.^c A single 14-day course of doxycycline is not routinely associated with tooth staining.^d Rifampin is not a protein synthesis inhibitor; it may also be used in combination therapy based on in vitro synergy.

APPENDIX 4 Triple Therapy for Systemic Anthrax (Anthrax Meningitis or Disseminated Infection and Meningitis Cannot Be Ruled Out) for Children 1 Month of Age and Older

1. A bactericidal antimicrobial (fluoroquinolone)

Ciprofloxacin, 30 mg/kg/day, intravenously (IV), divided every 8 h (not to exceed 400 mg/dose)^a

OR

Levofloxacin <50 kg: 16 mg/kg/day, IV, divided every 12 h (not to exceed 250 mg/dose); >50 kg: 500 mg, IV, every 24 h

OR

Moxifloxacin 3 mo to <2 y: 12 mg/kg/day, IV, divided every 12 h (not to exceed 200 mg/dose)

2–5 y: 10 mg/kg/day, IV, divided every 12 h (not to exceed 200 mg/dose)

6–11 y: 8 mg/kg/day, IV, divided every 12 h (not to exceed 200 mg/dose)

12–17 y, ≥45 kg body weight: 400 mg, IV, once daily

12–17 y, <45 kg body weight: 8 mg/kg/day, IV, divided every 12 h (not to exceed 200 mg/dose)

PLUS

2. A bactericidal antimicrobial (β-lactam or glycopeptide)

a. For all strains, regardless of penicillin susceptibility testing or if susceptibility is unknown

Meropenem, 120 mg/kg/day, IV, divided every 8 h (not to exceed 2 g/dose)

OR

Imipenem/cilastatin,^b 100 mg/kg/day, IV, divided every 6 h (not to exceed 1 g/dose)

OR

Doripenem,^c 120 mg/kg/day, IV, divided every 8 h (not to exceed 1 g/dose)

OR

Vancomycin, 60 mg/kg/day, IV, divided every 8 h

b. Alternatives for penicillin-susceptible strains

Penicillin G, 400 000 U/kg/day, IV, divided every 4 h (not to exceed 4 MU/dose)

OR

Ampicillin, 400 mg/kg/day, IV, divided every 6 h (not to exceed 3 g/dose)

PLUS

3. A Protein Synthesis Inhibitor

Linezolid^d: <12 y old: 30 mg/kg/day, IV, divided every 8 h ≥12 y old: 30 mg/kg/day, IV, divided every 12 h (not to exceed 600 mg/dose)

OR

Clindamycin, 40 mg/kg/day, IV, divided every 8 h (not to exceed 900 mg/dose)

OR

Rifampin,^e 20 mg/kg/day, IV, divided every 12 h (not to exceed 300 mg/dose)

OR

Chloramphenicol,^f 100 mg/kg/day, IV, divided every 6 h

Duration of therapy: for 2–3 wk or greater, until clinical criteria for stability are met (see text). Will require prophylaxis to complete an antimicrobial course of up to 60 days from onset of illness (see Appendix 1).

Systemic anthrax includes anthrax meningitis; inhalation anthrax; or injection, gastrointestinal, and cutaneous anthrax with systemic involvement, extensive edema, or lesions of the head or neck.

Children with altered mental status, signs of meningeal inflammation, or focal neurologic deficits should be considered to have CNS infection if CSF examination is not possible. Normal CSF may not completely exclude deep brain hemorrhage/abscess.

Bold font: preferred antimicrobial agent.

Normal font: alternative selections are listed in order of preference for therapy for patients who cannot tolerate first-line therapy or if first-line therapy is unavailable.

Doses are provided for children with normal renal and hepatic function. Doses may vary for those with some degree of organ failure.

^a A 400-mg dose of ciprofloxacin, IV, provides an equivalent exposure to that of a 500-mg ciprofloxacin oral tablet.

^b Increased risk of seizures associated with imipenem/cilastatin therapy.

^c Doripenem is approved in Japan at this dose for the treatment of community-acquired bacterial meningitis.

^d Linezolid should be used with caution in patients with thrombocytopenia, as it may exacerbate it. Linezolid use for >14 days carries additional hematopoietic toxicity.

^e Rifampin is not a protein synthesis inhibitor; it may also be used in combination therapy based on in vitro synergy for some strains of staphylococci. Not evaluated for *B anthracis*.

^f Should be used only if other options are not available, because of toxicity concerns.

APPENDIX 5 Oral Follow-up Combination Therapy for Severe Anthrax (for Children 1 Month of Age and Older)**1. A bactericidal antimicrobial****a. For all strains, regardless of penicillin susceptibility or if susceptibility is unknown****Ciprofloxacin, 30 mg/kg/day, by mouth (PO), divided every 12 h (not to exceed 500 mg/dose)**

OR

Levofloxacin <50 kg: 16 mg/kg/day, PO, divided every 12 h (not to exceed 250 mg/dose) ≥50 kg: 500 mg, PO, given every 24 h

OR

b. Alternatives for penicillin-susceptible strains**Amoxicillin, 75 mg/kg/day, PO, divided every 8 h (not to exceed 1 g/dose)**

OR

Penicillin VK, 50–75 mg/kg/day, PO, divided every 6 to 8 h

PLUS**2. A protein synthesis inhibitor****Clindamycin^a 30 mg/kg/day, PO, divided every 8 h (not to exceed 600 mg/dose)**

OR

Doxycycline^b <45 kg: 4.4 mg/kg/day, PO, divided every 12 h (not exceed 100 mg/dose) ≥45 kg: 100 mg, PO, given every 12 h

OR

Linezolid^c (non-CNS infection dose):

<12 y old: 30 mg/kg/day, PO, divided every 8 h

≥12 y old: 30 mg/kg/day, PO, divided every 12 h

(not to exceed 600 mg/dose)

Duration of therapy: to complete a treatment course of 14 days or greater. May require prophylaxis to complete an antimicrobial course of up to 60 days from onset of illness (see Appendix 1).

Severe anthrax includes inhalation anthrax; injection, gastrointestinal, or cutaneous anthrax with systemic involvement, extensive edema, or lesions of the head or neck.

Bold font: preferred antimicrobial agent.

Normal font: alternative selections are listed in order of preference for therapy for patients who cannot take first-line therapy or if first-line therapy is unavailable.

Doses are provided for children with normal renal and hepatic function. Doses may vary for those with some degree of organ failure.

^a Based on in vitro susceptibility data rather than studies of clinical efficacy.^b A single 14-day course of doxycycline is not routinely associated with tooth staining.^c Linezolid should be used with caution in patients with thrombocytopenia, as it may exacerbate it. Linezolid use for >14 days carries additional hematopoietic toxicity.

THESE ANTIMICROBIALS AND DOSAGES HAVE NOT BEEN REVIEWED OR APPROVED BY THE FDA FOR USE IN NEWBORN INFANTS, UNLESS SPECIFICALLY NOTED. THESE DOSES ARE PROVIDED ONLY AS GUIDANCE DURING AN EMERGENCY BIOLOGICAL WEAPON EVENT, ON THE BASIS OF AVAILABLE LITERATURE OR EXTRAPOLATION FROM PHARMACOKINETIC DATA FROM OLDER CHILDREN, WITH KNOWLEDGE OF MATURATION OF NEONATAL CLEARANCE MECHANISMS.

Dosing guidance for anthrax in newborn infants has not been proposed earlier because of the paucity of pharmacologic data describing kinetics, safety, and efficacy and the broad range of developmental changes that will affect therapy in this immature population. This guidance accommodates not only term newborn infants but also neonates who may be born at 32 wk postmenstrual age (PMA). For neonates of earlier gestational age, please consult with a neonatologist, pharmacologist, or infectious diseases physician for appropriate dosing. Doses are provided for newborns with developmentally appropriate renal and hepatic function. Doses may vary for those with some degree of organ failure.

By convention, the neonatal period ends 28 d (4 wk) after birth, but at 4 wk of age, the physiologic maturity of a preterm infant lags significantly behind a term infant. Preterm infants continue to undergo developmental changes through 44 wk PMA that affect pharmacokinetics, with maturation of mechanisms of renal elimination and hepatic enzymatic drug inactivation that occur at different rates for different antimicrobial agents, some closely linked to PMA or chronologic age, but most demonstrate aspects of both. Hence, we provide guidance for all newborn infants through 44 wk PMA while recognizing that many physiologic processes mature during this developmental period and that new dosing recommendations are likely to follow as additional data become available. Should these medications be required for treatment or prophylaxis, it will be especially important to plan prospectively to monitor serum/plasma concentrations in a systematic fashion to acquire good data that relate dose of drug to concentration, efficacy, and occurrence of adverse effects.

Antimicrobial-related adverse effects are always possible; however, the benefit of antimicrobial therapy for life-threatening infection justifies assuming greater risk during therapy. In general, the frequency and severity of adverse events seem to be less, rather than more, in neonates.

Duration of therapy: For ≥ 2 –3 wk, until clinical criteria for stability are met (see text). Will require prophylaxis to complete an antibiotic course of up to 60 days from onset of illness (see Appendix 6E).

div, XXX; q, every.

Bold font: preferred antimicrobial agent.

Normal font: alternative selections are listed in order of preference for therapy for patients who cannot tolerate first-line therapy, or if first-line therapy is unavailable.

^a Severe anthrax includes anthrax meningitis; inhalation anthrax; or injection, gastrointestinal, or cutaneous anthrax with systemic involvement; extensive edema; or lesions of the head or neck.^b Neonates with irritability, vital sign instability, bulging fontanel, or focal neurologic deficits should be considered to have CNS infection if CSF examination is not possible. Normal CSF may not completely exclude deep brain hemorrhage/abscess.^c Increased risk of seizures associated with imipenem/cilastatin therapy.^d Doripenem is approved in Japan at this dose for the treatment of community-acquired bacterial meningitis in older children.^e Linezolid should be used with caution in newborn infants with thrombocytopenia, as it may exacerbate it. Linezolid use for >14 days may be associated with additional hematopoietic toxicity.^f Rifampin is not a protein synthesis inhibitor; it also may be used in combination therapy based on in vitro synergy.^g Should be used only if other options are not available because of toxicity concerns; obtain chloramphenicol serum concentrations, if possible.^h Safety data are unavailable for fluoroquinolones for duration of therapy >30 days. Tendinopathy and arthralgia have been reported with fluoroquinolone antimicrobial agents in ambulating animals and humans. These problems appear to be much less, if they occur at all, in pediatric patients, especially in newborn infants.^{54,112,113}ⁱ On the basis of in vitro susceptibility data rather than studies of clinical efficacy.^j A single 10- to 14-day course of doxycycline is not routinely associated with tooth staining in older children but may stain developing teeth in neonates.^{40,41,114}^k Be aware of the possibility of emergence of penicillin-resistance during monotherapy with amoxicillin or penicillin.

APPENDIX 7 Diagnostic Assessment and Monitoring for Systemic Anthrax (Based on Recommendations for Adults)

Test	Unique Findings in Systemic Anthrax Infections	
	Initial	Serial Monitoring
Complete blood cell count	Marked hemoconcentration; thrombocytopenia may not be present; white blood cell count frequently normal	Anemia can suddenly develop; thrombocytopenia onset often associated with hemolytic anemia; leukocytosis usually not seen until severe sepsis stage
Electrolytes, blood urea nitrogen, lactate	Decreased sodium; bicarbonate can be normal even with severe sepsis; increased blood urea nitrogen	
Liver panel, serum albumin	Mild transaminitis; hypoalbuminemia related to acute infection	
Prothrombin time (PT), partial thromboplastin time (PTT), D-dimer, Fibrinogen	Normal PT/PTT at admission does not exclude coagulopathy or disseminated intravascular coagulopathy	Low threshold for disseminated intravascular coagulation workup, including haptoglobin, lactate dehydrogenase, fibrin split products. If evidence of hemolytic anemia, assess ADAMTS 13 (von Willebrand factor–cleaving protease).
Erythrocyte sedimentation rate, C-reactive protein	Useful for characterizing inflammatory response	
Gram stain, cultures, serum for toxin assays	Any accessible fluid: blood, sputum, cerebrospinal, urine, wound, gastric ulcers	Cultures usually negative after antimicrobial agents, but toxin may be detectable at multiple time points.
Cardiac enzymes (troponin) +/-B-type natriuretic peptide	Troponin leak as a result of increased cardiac demands from acute infection (especially if atrial fibrillation with rapid ventricular response)	
Electrocardiogram/continuous cardiorespiratory monitoring telemetry	Atrial fibrillation with rapid ventricular response commonly observed.	
Posterior-anterior and lateral chest radiograph	Any abnormality: mediastinal widening may not be seen in inhalation and pleural effusion can be subtle	Daily chest radiographs or other thoracic imaging until pleural effusions are stable or decreasing
Chest CT	Evaluate for severity of pleural effusions, presence of mediastinal widening, and to rule out thromboembolic disease with CT angiography	Repeat if significant clinical status change. Ultrasonography of the chest may be useful for following pleural effusion.
Lumbar puncture	With severe or systemic disease, perform as soon as clinically feasible; meningeal signs are usually not present until late stage, if meningitis is present.	—
Other imaging	As relevant to site of exposure; to evaluate edema, inflammation, and necrosis	—
Echocardiogram	Evaluate for pericardial effusion in addition to myocardial dysfunction.	

APPENDIX 8 Recommendations for Compatibility of Antimicrobial Agents and Breastfeeding

Antimicrobial Agent	US National Library of Medicine LACTMED ^a	Briggs' Pregnancy and Lactation ^b
Amoxicillin	Acceptable to use	Compatible
Ampicillin	Acceptable to use	Compatible
Chloramphenicol	Alternate drug is preferred	Potential toxicity
Ciprofloxacin	Short-term ^c use is acceptable	Limited human data—potential toxicity
Clindamycin	Not a reason to discontinue breastfeeding Alternate drug is preferred	Compatible
Doxycycline	Short-term use is acceptable Avoid prolonged ^d or repeat courses	Compatible
Imipenem	Acceptable to use	Limited human data—probably compatible
Levofloxacin	Short-term ^c use is acceptable	Limited human data—probably compatible
Linezolid	Not a reason to discontinue breastfeeding	No human data—potential toxicity
Meropenem	Not expected to cause adverse effect	No human data—probably compatible
Moxifloxacin	Short-term ^c use is acceptable	No human data—probably compatible
Penicillin	Acceptable to use	Compatible
Rifampin	Not expected to cause adverse effects	Compatible

Pediatric Anthrax Clinical Management: Executive Summary

.....

- *Clinical Report*

CLINICAL REPORT

Pediatric Anthrax Clinical Management: Executive Summary

The use of *Bacillus anthracis* as a biological weapon is considered a potential national security threat by the US government. *B anthracis* has the ability to be used as a biological weapon and to cause anthrax, which can rapidly progress to systemic disease with high mortality in those who are untreated. Therefore, clear plans for managing children after a *B anthracis* bioterror exposure event must be in place before any intentional release of the agent. This document provides a summary of the guidance contained in the clinical report (appendices cited in this executive summary refer to those in the clinical report) for diagnosis and management of anthrax, including antimicrobial treatment and postexposure prophylaxis (PEP), use of antitoxin, and recommendations for use of anthrax vaccine in neonates, infants, children, adolescents, and young adults up to the age of 21 years (referred to as “children”).

Key considerations in a mass *B anthracis* exposure scenario include the following:

1. Public health authorities will determine the presence and extent of a bioterror event. Information of importance to health care providers and the public will be made available as soon as possible by the Centers for Disease Control and Prevention (CDC), including information posted on the CDC Anthrax Web site: www.cdc.gov/anthrax.
2. Within 48 hours of exposure to *B anthracis* spores, public health authorities plan to provide a 10-day course of antimicrobial prophylaxis to the local population, including children likely to have been exposed to spores (Appendix 1). Public health officials will provide information about points of dispensing locations that will distribute antibiotic agents.
3. Within 10 days of exposure, public health authorities plan to further define those who have had a clear and significant exposure and will require an additional 50 days of antimicrobial PEP, as well as beginning the 3-dose anthrax vaccine, anthrax vaccine adsorbed (AVA [BioThrax, Emergent BioSolutions, Rockville, MD]) series for children. Because there are insufficient data for the anthrax vaccine in children, it will be made available under an Investigational New Drug protocol. For children younger than 6 weeks of age (who are not candidates for AVA), antimicrobial prophylaxis should begin immediately, but the vaccine series should be delayed until the child reaches 6 weeks of age.
 - A local adverse event after receiving a previous dose of AVA is not a contraindication to receiving additional doses, although the

subsequent dose should be administered at an alternate site and closely monitored.

- Although not strictly contraindicated, AVA should not be coadministered routinely with standard childhood vaccinations during an anthrax event. Immunization of children exposed to aerosolized *B anthracis* spores with AVA is a priority, above routine immunizations. Although data are not available in children regarding the types and frequency of adverse events after immunization, or whether administering AVA as soon as a few days after the receipt of routine immunizations will lead to an increased frequency of adverse events, the benefits of AVA in children exposed to aerosolized *B anthracis* spores are currently believed to outweigh these risks. Routine immunizations should resume 4 weeks after the last AVA dose.
4. Anthrax may occur in different clinical forms, any of which may progress to systemic disease. Treatment will vary by clinical manifestation. The diagnosis of anthrax can be made by physical findings, as described in the clinical report, in conjunction with Gram stain and culture, or by a rapid molecular test for anthrax, currently under development at the CDC. The CDC Web site provides guidance on diagnostic specimens to obtain for the different clinical presentations of anthrax, at www.cdc.gov/anthrax/labs/recommended_specimen.html. Guidance for diagnostic assessment and monitoring with clinical, laboratory and imaging evaluations is also provided in the clinical report (Appendix 7).
 - Cutaneous anthrax without systemic involvement that occurs in the context of an anthrax bioterror event should be treated with a single oral antimicrobial agent (Appendix 2).
 - Inhalation, gastrointestinal, or other systemic disease without meningoencephalitis should be treated with at least 2 intravenous antimicrobial agents: a bactericidal agent and a protein synthesis inhibitor (Appendix 3), with the provision of oral step-down therapy for children whose signs and symptoms of systemic infection have resolved (Appendix 5).
 - Systemic disease with possible or confirmed meningoencephalitis should be treated with 3 intravenous antimicrobial agents with adequate central nervous system penetration, including 2 bactericidal agents and a protein synthesis inhibitor (Appendix 4), for at least 2 weeks, and until all clinical signs and symptoms, supported by laboratory and imaging data, document resolution of inflammation associated with the infection.
 - Antimicrobial agent doses for term and preterm neonates are provided in Appendix 6 for cutaneous and systemic infections as well as for PEP.
 - Anthrax systemic infection is generally not considered contagious, and Standard Precautions should be used for routine patient care. Cutaneous anthrax may be contagious on direct contact of the lesions for the first 24 hours of effective antimicrobial therapy, supporting the use of Contact Precautions during that time.
 5. Either Anthrax Immune Globulin or raxibacumab antitoxin is indicated in patients with anthrax systemic disease, particularly nonmoribund children with severe disease, including those with new onset of organ system failure. Dosing guidelines for children will be available on package labels at the time antitoxin is shipped to the site of the bioterror exposure. Raxibacumab is approved by the US Food and Drug Administration for use in adults and children for the treatment or prevention of anthrax. On the basis of animal studies, pediatric population pharmacokinetic modeling was performed by the manufacturer, and proposed weight-based doses for children are provided on the package label (www.accessdata.fda.gov/drugsatfda_docs/label/2012/125349s000lbl.pdf). Anthrax Immune Globulin is not currently approved by the Food and Drug Administration and will need to be administered under an Investigational New Drug application or Emergency Use Authorization during a mass exposure event.
 6. Corticosteroids should be used in children with more severe systemic disease, particularly those with meningoencephalitis, in doses that are consistent with those currently used for meningitis (dexamethasone, 0.6 mg/kg per day in divided doses every 6 hours for 4 days).
 7. Once therapy has been completed for any form of systemic or cutaneous anthrax infection in children involved in an aerosol *B anthracis* dispersal event, appropriate oral antimicrobial agents as PEP should be provided to complete a full 60 days of therapy.
 8. Unless breastfeeding mothers have untreated cutaneous lesions on their breasts, breastfeeding should continue for infants of mothers who require antimicrobial treatment or prophylaxis or anthrax vaccine (Appendix 8).
 9. To optimally manage children during an anthrax bioterror event, the

ready availability and bidirectional flow of information between public health officials and pediatric health care providers, as well as clear recommendations and consistent messaging to the public from public health officials and

health care providers will be extremely important. Information will be provided on the CDC Web site, www.cdc.gov/anthrax, as well as through the American Academy of Pediatrics. As pediatricians are trusted sources of information,

the medical home can support adherence to prophylactic antimicrobial regimens, decrease panic among parents and caregivers, and possibly save lives in the midst of a public health emergency.

Pediatric Care Recommendations for Freestanding Urgent Care Facilities

.....

- *Policy Statement*

POLICY STATEMENT

Pediatric Care Recommendations for Freestanding Urgent Care Facilities

abstract

FREE

Treatment of children at freestanding urgent care facilities has become common in pediatric health care. Well-managed freestanding urgent care facilities can improve the health of the children in their communities, integrate into the medical community, and provide a safe, effective adjunct to, but not a replacement for, the medical home or emergency department. Recommendations are provided for optimizing freestanding urgent care facilities' quality, communication, and collaboration in caring for children. *Pediatrics* 2014;133:950–953

INTRODUCTION

Urgent care for children, as a segment of the current health care industry, continues to grow in number of facilities, variety, and scope. The Urgent Care Association of America estimates that there are 4500 urgent care facilities (private communication, Urgent Care Association of America, 2013) at which more than 150 million adult and pediatric visits occur annually in the United States.¹ The descriptors “urgent care” and “urgent care facility (or center)” have been used in a variety of ways, from describing after-hours or sick visits provided in a primary care office or clinic to the provision of hospital-based acute care in a non-emergency department setting. This policy statement addresses acute care provided to sick or injured children in a freestanding setting specifically designated for that purpose and does not address hospital-based urgent care facilities, hospital-based or freestanding emergency departments, or retail-based clinics.²

BACKGROUND

Urgent care typically focuses on providing acute assessment and management of mildly or moderately sick or injured patients, with an emphasis on rapid service and low cost. Freestanding urgent care facilities typically provide unscheduled visits but may also allow patients and families to make an appointment. Business models include individual businesses, franchises, affiliates of a specific health insurer, or subsidiaries of a hospital, among others. Facilities operating as part of a hospital system will probably fall within that larger administrative structure and include shared computerized imaging, laboratory facilities, medical records, and other resources. Most urgent care facilities have at least 1 physician on staff.³ Plain

radiography, suturing of uncomplicated lacerations, splinting of uncomplicated musculoskeletal injuries, and simple laboratory tests are typically offered. Some provide such nonacute services as immunizations and preparticipation sports physical examinations. One of the principal challenges of urgent care is maintaining an appropriate and predetermined scope of practice, because patients with true emergencies may seek care at urgent care facilities; this confusion is probably exacerbated by varying definitions of urgent care. Regulation of freestanding urgent care centers varies greatly between the states, ranging from little oversight to actual prohibition of the use of the term “urgent care” except by emergency centers.⁴ Screening of all patients for emergency medical conditions and other requirements of the Emergency Medical Treatment and Labor Act apply to hospital-owned freestanding urgent care facilities if either the center is licensed as an emergency department, it is advertised as providing care for emergency medical conditions on an urgent basis, or at least one-third of its outpatient visits are for treatment of emergency medical conditions, as judged by the Centers for Medicare and Medicaid Services, on an urgent basis without a previously scheduled appointment.^{5,6}

RECOMMENDATIONS

As the role of freestanding urgent care facilities in pediatric care evolves, it is important that they maintain the highest standards of care. Despite the growth in pediatric urgent care, there is little existing literature beyond professional policy statements and industry white papers on the subject. Research on the nature, scope, quality, and outcomes of pediatric urgent care is scant.^{3,7,8} With these limitations, the

recommendations here represent expert consensus by leaders in pediatric emergency medicine and related fields. Given its growing importance, a better understanding of pediatric urgent care should be an important focus for health service researchers.

Emergency Preparedness

Freestanding urgent care facilities serving children should be capable of providing timely assessment, initial resuscitation, and stabilization and be able to initiate transfer of pediatric patients who need a higher level of care. This includes children with medical, traumatic, and behavioral or mental health emergencies. Staff members at freestanding urgent care facilities should have the training, experience, and skills necessary to initiate pediatric life support during all hours of operation. Simulation or mock codes, with scenarios that are complete from patient presentation to departure, are often an important component of pediatric emergency preparedness. Triage, transfer, and transport agreements should be prearranged with definitive care facilities that are capable of providing the appropriate level of care based on the acuity of illness or injury of the child. Local emergency medical services providers should be familiar with the facility's physical plant and should familiarize urgent care facility staff with their pediatric capabilities. Programs to monitor and improve the quality of care for children with emergencies should be in place. Although written for the primary care provider, the American Academy of Pediatrics policy statement “Preparation for Emergencies in the Offices of Pediatricians and Pediatric Primary Care Providers” offers excellent guidance for preparation, recognition, and response to children needing emergency care in the urgent care facility setting.⁹

Scope of Care

Freestanding urgent care facility operators must give careful thought and planning to the scope of care that they can and should provide to pediatric patients. This includes evidence-based, patient- and family-centered, predetermined approaches to common pediatric complaints, including fever, asthma exacerbations, lacerations, gastrointestinal tract complaints, potential fractures, and other musculoskeletal injuries. Principles guiding the extent of evaluation and management of other complaints should be established. Urgent care facilities should be capable of managing children with special needs. Recognition and management of child abuse or neglect and other aspects of interpersonal violence should be addressed. Guidance regarding conditions that are or are not appropriate to the facility should be readily available to the public, including parents, referring physicians, and other referral sources, such as triage nurse telephone services. This should include guidance on when even a common pediatric complaint is too severe to be appropriate for urgent care, such as injuries or illnesses that may warrant hospitalization, advanced imaging, or invasive procedures. The timing and availability of child-appropriate equipment, on-site and off-site laboratory testing, and imaging must be taken into consideration. Planning should include setting limits on the intensity and scope of care and predetermined systems for handovers of care when those limits are reached or the facility is closing.

Facilities must have predetermined plans for addressing requests for patient care, including those involving children with emergency medical conditions, occurring before or after usual hours of operation, including when staff members are physically

present. Signage and directions to nearby emergency facilities can be especially helpful to those seeking care when no facility staff are present.

The Medical Home

Urgent care facilities should complement and support the medical home model,¹⁰ providing some services not routinely available in the medical home and providing an alternative for acute care should the medical home be unavailable. They should not routinely provide continuity care to children and should avoid appearing as a replacement for the primary care provider. Urgent care facilities should collaborate with primary care providers as referral centers for patients with acute health concerns. Referring providers should provide necessary clinical information to the freestanding urgent care facility and be available to provide consultation and context for their patients' management. Whether a patient is referred or not, appropriate records should be kept. Communication with the medical home should be prompt and seamless. Medical homes must provide easily accessed channels for this communication. Providers who refer children to a freestanding urgent care facility should verify adherence to these recommendations with the facility's leadership and should expect high-quality care for their patients.

Staffing

Freestanding urgent care facilities serving children must be staffed by providers and staff with the training and experience to manage children who are seeking urgent care and to initially assess and manage, resuscitate if needed, and transfer children who are seeking emergency care from the urgent care setting. Educational opportunities directed at clinicians or

administrators providing urgent care for children are needed. Nonphysician providers should have meaningful oversight by appropriate physicians; even when not legally required, collaboration with a qualified physician is desirable. A clinician–manager empowered to address off-hours questions about imaging, laboratory tests, prescriptions, and the like should be designated.

Participation in Systems of Care

Freestanding urgent care facilities provide service that can enhance pediatric care in many communities. Therefore, they should be an integral part of community systems of care. Area health departments, medical societies, and other professional groups should provide appropriate lines of communication and avenues for this participation. Facility-specific disaster preparedness preparations should be in place. In addition, urgent care facilities may be important participants in local and regional disaster plans by providing syndromic surveillance to assist in identification of disasters and epidemics, pediatric primary care services when disaster disrupts the medical home, and countermeasures and patient education in the case of actual or potential outbreaks.

Urgent care facilities should have transfer arrangements with area hospitals capable of providing pediatric or adult emergency care as necessary. Providers should be able to distinguish, ideally via predetermined criteria and in conjunction with families, which patients need emergency ambulance transfers, which need non-emergency ambulance-based transfers, and which may be transferred by other means, such as private vehicle. Planned coordination with local emergency medical services is essential. Appropriate payment should be made to both facilities when a patient is

transferred from a medical home to an urgent care facility or from an urgent care facility to an emergency department or other facility.

Medical professionals providing oversight to freestanding urgent care facilities serving children should regularly review facility adherence to this policy statement. Accreditation by external reviewers of urgent care facilities serving children should include meaningful assessment of quality measures and performance of appropriate pediatric care.

CONCLUSIONS

Well-managed freestanding urgent care facilities can enhance the provision of urgent services to the children of their communities, be integrated into the medical community, and provide a safe, effective adjunct to, but not a replacement for, the medical home. Urgent care facilities serving children should be able to rapidly assess, begin stabilization, and initiate transfer of children with emergencies. Consistent oversight, planning, and quality monitoring and improvement are crucial. The scope of care offered to children should be well defined and well communicated. Providers and staff must have the training and experience to manage children. There remains a great need for research on the role of urgent care in pediatrics. Educational opportunities at the student, resident, fellow, or continuing medical education level involving pediatric urgent care are minimal and should be developed as more and more pediatricians and other health care providers are employed by, provide oversight to, or work collaboratively with urgent care facilities. Accreditation of urgent care facilities serving children should include meaningful assessment of quality measures and performance of appropriate pediatric care.

- *Policy Statement*

POLICY STATEMENT

The Pediatrician's Role in the Evaluation and Preparation of Pediatric Patients Undergoing Anesthesia

abstract

FREE

Pediatricians play a key role in helping prepare patients and families for anesthesia and surgery. The questions to be answered by the pediatrician fall into 2 categories. The first involves preparation: is the patient in optimal medical condition for surgery, and are the patient and family emotionally and cognitively ready for surgery? The second category concerns logistics: what communication and organizational needs are necessary to enable safe passage through the perioperative process? This revised statement updates the recommendations for the pediatrician's role in the preoperative preparation of patients. *Pediatrics* 2014;134:634–641

INTRODUCTION

Primary care providers, including pediatricians, are frequently called on to evaluate and psychologically prepare patients and families before a child undergoes a procedure requiring anesthesia or sedation. This policy statement identifies that primary care provider's preoperative goals of care are as follows: to clearly define the child's medical issue; to delineate the physiologic effects and limitations imposed by each condition; and to optimize the management of any comorbid conditions. Furthermore, the policy recommends that pediatricians facilitate essential communication about the historical, physical, and laboratory findings in children with unusual or complex medical histories with the anesthesiologist and/or surgeon to ensure safe perioperative care.

The objectives of the present statement were twofold:

1. to describe to pediatricians the issues of concern to anesthesiologists and surgeons to improve the effectiveness of medical consultations in preparing pediatric patients and families for the perioperative period; and
2. to present information that will encourage and facilitate communication among surgeons, anesthesiologists, medical subspecialists, pediatricians, and other primary care providers.

ROLE OF THE PEDIATRICIAN IN THE PREOPERATIVE PREPARATION

General Approach

The primary steps in preoperative preparation are to determine whether the child is in the best possible state of health, given the child's underlying

medical condition, and to manage any concurrent acute interceding illness. The key concept is that the patient's medical condition should be "optimized" when he or she presents to the operating room (OR). The American Society of Anesthesiologists has an established risk-stratification system (Table 1).¹ Class 1 and class 2 are considered low risk. The goal of preoperative preparation is to bring patients from a higher risk stratum to a lower one when possible or, at least, to ensure that the patient is in the best condition within his or her physical status category.

The second step in preparing patients is to educate the family about the process of going to the OR and to help them advocate for a process that works best for them and their child. Preparation for surgery has many facets.² There is no "standard" procedure for preparing children for surgery, and available resources vary greatly from one institution to another. Options for family and child preparation may include Internet-based information, tours of the perioperative environment, coping/relaxation instruction, and interventions by child life specialists.³ General information can be found in video or book format, although content and accuracy vary.⁴ Some hospitals allow parental presence during induction of anesthesia (PPIA). However, PPIA is

not a universal practice and is always at the discretion of the anesthesiologist involved in a particular case. Although beneficial to some families and practiced in a number of centers, PPIA is not effective in relieving anxiety in the children, especially if the parent(s) is anxious.^{5–7} PPIA can be stressful to parents, and the pediatrician should thus make sure families know that PPIA may be an option but is never mandatory.

In many cases, children and their families benefit from preoperative sedation. Younger children (2–5 years of age) and patients who have been to the OR before are at higher risk of being stressed and uncooperative during the induction of anesthesia.⁸ In addition, some patients will suffer from postoperative behavioral changes, including sleep difficulties, which may present to the pediatrician in the weeks after surgery. Recent studies have concluded that the likelihood of these maladaptive behaviors is higher if the child is anxious preoperatively.⁹ Pediatricians need to be aware of the policies surrounding PPIA and preoperative sedation at the operative facilities to which they refer their patients. Parents should be encouraged to ask the anesthesia team about available options for preinduction sedation and PPIA. This information can empower them to better advocate for their child.

Most anesthesia departments will obtain informed consent for the anesthesia, separate from that for the procedure. For most minors, the parents will give informed consent (technically, informed permission). Adolescents can participate, to varying extents, in the process by giving assent to care. Pediatricians should encourage adolescent patients to ask questions to make sure they understand what is planned. In cases in which the patient can make no meaningful objection (emergency or other nonelective procedure), then the option to assent or decline care should not be presented.¹⁰

Currently, there is concern about the potential negative effects of general anesthesia in neurologic development, especially in children aged <2 years who undergo multiple procedures.^{11–13} Pediatricians need to stay informed of this evolving area of inquiry. Although no firm guidelines exist, some experts have proposed delaying purely elective procedures as long as possible.¹⁴ The long-term effects of anesthesia on the developing human brain are still unknown, but there is broad agreement that limiting exposure to general anesthesia in infants is a wise policy.

The Preanesthesia Consultation

Patients with complex medical and surgical conditions can benefit from a thorough preoperative assessment by an anesthesia care provider. Ideally, these preoperative evaluations take place in advance of the day of surgery, to avoid last-minute cancellations that occur because of missing data critical to optimizing the patient's condition for surgery. Many anesthesia departments have consultation clinics to provide a common touch point for the pediatrician, anesthesiologist, surgeon, consultants, and family. If no such clinic is available, then the pediatrician and family should pose their questions about the perioperative preparation of the child directly to an anesthesiologist in the department (or group) that will be caring for the patient. Because the specific anesthesiologist assigned to the case may not be known more than a day ahead of the surgery, contact with an anesthesia provider will often be made through the anesthesiology department. Examples of criteria for preoperative anesthesia consultation are shown in Table 2.^{15,16}

Information of Importance to the Anesthesiologist and Surgeon

History of the Present Illness

This part of the history is usually clear, but medical factors leading to the need

TABLE 1 ASA Physical Status Classification System

ASA physical status 1: A normal healthy patient
ASA physical status 2: A patient with mild systemic disease
ASA physical status 3: A patient with severe systemic disease
ASA physical status 4: A patient with severe systemic disease that is a constant threat to life
ASA physical status 5: A moribund patient who is not expected to survive without the operation
ASA physical status 6: A declared brain-dead patient whose organs are being removed for donor purposes

TABLE 2 Examples of Patients Who Should Be Seen for a Preanesthesia Consultation^{15,16}

Children who are having the following operations:

- Complex spine surgeries
- Airway reconstruction
- Major chest surgery (include cardiac)
- Major abdominal surgery
- Major neurosurgery

Children with the following medical conditions:

- Complex heart disease, history of heart failure, or pacemaker dependence
- Serious respiratory disease, such as severe asthma and cystic fibrosis and patients requiring ventilator support or oxygen therapy
- Complex airway patients, including those with craniofacial syndromes and those with a history of being difficult to intubate
- Patients with severe obstructive sleep apnea
- Muscular dystrophy, mucopolysaccharidoses, or any progressive neuromuscular disorders
- Cervical spine instability and patients in a neck brace
- Hunter syndrome and Hurler syndrome
- Morbid obesity
- Living related organ donors
- Transplant recipients
- Patients presenting with complex ethical issues; for example, religious objections to blood transfusion or end-of-life decisions (eg, DNR orders)
- Complex pain or psychosocial issues that affect perioperative care

for surgery are important, including the intended effect of the operation on health and future care.

Medical History

The details of the patient's medical history are not always apparent to the perioperative care team; therefore, the pediatrician's detailed knowledge of the patient's medical history is an especially important area in which he or she can improve overall care for a patient. For example, pediatrician input has been shown to frequently modify the perioperative plan in children undergoing dental procedures.¹⁷ Planning for anesthesia benefits from communication about neurologic development and function, airway anomalies (eg, difficult intubations, history of airway surgery), cardiac and pulmonary function (including sleep apnea as well as

lung disease), coagulation history, endocrine and renal diseases, and history of exposure to chronic opioids, anesthetics, and sedatives. Motion sickness is a risk factor in adults for postoperative nausea and vomiting (PONV) and is very likely a predictor in children as well. This history should be noted, as should a history of PONV with previous surgeries.¹⁸ General psychosocial history can guide perioperative management. Conditions such as severe anxiety or posttraumatic stress disorder or conditions that impair the child's ability to process information (eg, attention-deficit disorder) or interact with strangers under stressful conditions (eg, oppositional defiant disorder, autism spectrum disorders) should be conveyed to the anesthesia care team. Before elective procedures, consultation with a psychologist to aid in preparing the family and child with these severe cognitive and emotional disorders may be helpful as well.

Medications

The most common problem regarding perioperative medication administration is the misunderstanding that nil per os (NPO, or withholding oral foods/fluids) intervals do not necessarily include medications. Most regularly prescribed medications can be taken with a sip of water on the day of surgery and not violate NPO standards. Conversely, many nonprescription medications and herbal supplements may pose potential risk of bleeding or drug interaction.^{19,20} Over-the-counter medications and supplements should be stopped before surgery, unless there is specific reason to continue them (eg, aspirin in certain patients with cardiac conditions). The exact timing will depend on the medication or supplement involved.

Family History

Four items of family history are particularly important: malignant hyperthermia (MH), prolonged paralysis after

receiving succinylcholine (pseudocholinesterase deficiency), bleeding diathesis, and PONV. In the cases of MH and pseudocholinesterase deficiency, appreciation of either of these entities will dictate the avoidance of specific anesthetic agents, the use of which can result in potentially catastrophic effects in predisposed patients. A family history of spontaneous or postsurgical bleeding may indicate the need for hematologic investigation before certain procedures. As mentioned previously, a family history of PONV is less specific than a history of MH, because influences are multifactorial, but this information may help the anesthesiologist address the family's questions regarding anesthetic technique and prophylactic medications.

Physical Examination

The pediatrician's examination sets a baseline against which the perioperative physical status can be compared. Highlighting neurologic findings, cardiac murmurs, rashes, wheezing, congenital anomalies, and vital signs is helpful to perioperative care providers.

Pertinent Laboratory Evaluation

There is no role for routine laboratory testing of healthy children undergoing procedure with minimal risk of blood loss or for neurologic, cardiac, or pulmonary compromise. Some centers require hemoglobin testing for infants and for patients having surgery in which blood loss is expected. In healthy children, laboratory and radiologic testing should be limited to situations in which the history or physical examination raises a specific possibility of risk. For patients with specific illnesses, testing serves the purpose of establishing a baseline and determination if the patient's underlying condition is appropriately controlled before inducing the perturbations of anesthesia and surgery.

Many institutions have policies that require preoperative pregnancy testing

for all postmenarcheal females on the morning of surgery. It is helpful to warn patients and families that this testing may take place and is not a personal judgment but rather a matter of routine.

SPECIAL ISSUES FOR PRIMARY HEALTH CARE PROVIDERS: ANESTHESIA AND COEXISTING HEALTH PROBLEMS

Cardiac Disease

A child with a new murmur that does not have the characteristics of an “innocent murmur” should be evaluated by a cardiologist to determine the presence of an intracardiac shunt and/or obstruction to flow.

Children with known congenital heart disease, such as a history of “repaired” tetralogy of Fallot or pulmonary hypertension, should be evaluated by a cardiologist before anesthesia; the time interval necessary depends on the severity of the child’s disease and/or the need for possible cardiac intervention before anesthesia to optimize the child’s physiologic condition. The management of anticoagulation for patients with prosthetic valves requires coordination with a cardiologist (and often a hematologist) well in advance of surgery. Note should be made of pacemakers (and any perioperative adjustments may be made by a cardiologist), pulmonary hypertension (degree and duration), and any unusual electrocardiographic findings (eg, prolonged QTc interval).^{21,22} Patients with any of these issues should have been evaluated by a pediatric cardiologist before anesthesia and surgery to ensure optimal condition and management during the perioperative period.

Airway Anomalies

Few things are more dangerous than difficulty in maintaining a patent airway or being unable to intubate a patient. Therefore, it is imperative that the pediatrician inform the anesthesia team

of all patients with airway disorders. “Red flag” conditions include: previous difficulties with intubation or mask ventilation, Pierre Robin syndrome, Treacher Collins syndrome, Goldenhar syndrome, Down syndrome, Klippel-Feil syndrome, mucopolysaccharidoses, previous airway or cervical spine surgery, prolonged neonatal intubation, and stridor at rest.

Respiratory Disease

Asthma, cystic fibrosis, and other chronic lower respiratory disease all merit mention in the preoperative evaluation. The following are important to the anesthesiologist: use of steroids in the recent past, a history of chest or airway surgery, a history of bronchopulmonary dysplasia, upper airway malformation, and history of sleep apnea. In an otherwise healthy child, the presence of an acute upper respiratory tract infection without systemic or lower respiratory tract symptoms is not usually grounds for cancellation of surgery. Conversely, upper respiratory tract infections that are accompanied by fever, wheezing, or productive cough are likely to lead to cancellation of elective procedures.^{23,24} Patients scheduled for nonemergent procedures who are recovering from respiratory illness in the previous 2 weeks are taken on a case-by-case basis; detailed information provided by the pediatrician concerning the chest and upper airway examination can be very helpful in determining the timing of surgery.

Central Nervous System

Patients with seizure disorders should take their anticonvulsants as scheduled. Notation of the type of seizure, medications, and a brief description of a typical seizure may aid perioperative care providers in recognizing a seizure and speed treatment. Any patient with a baseline neurologic deficit should have that deficit described so that changes could be recognized in the perioperative

period. Increased intracranial pressure (of any extent) has particular implications for perioperative care and should be noted in the history. For children at risk for cervical spine instability (eg, Down syndrome,²⁵ mucopolysaccharidoses,²⁶ severe Ehlers-Danlos syndrome), results of cervical spine radiographs or history of symptomatic instability should be clearly identified for the surgeon and anesthesiologist. Radiographic screening does not predict risk of cervical instability²⁷ in Down syndrome. Thus, all these patients are treated with caution, and parents can be assured that their child will have cervical spine precautions regardless of radiograph results.

Hematologic Disorders

Histories of patients with hemoglobinopathies, such as sickle cell disease, should include medications, any previous serious complications (eg, acute chest syndrome, splenic crisis, aplastic crisis, cholecystitis), and opioid treatment. For children with hemophilia, von Willebrand disease and other factor deficiencies and platelet disorders, a history of complications and treatment algorithms are critical. A plan for perioperative management should be coordinated with the child’s hematologist and clearly delineated. For children with factor V Leiden deficiency or other genetic thrombophilias that increase the risk of deep vein thrombosis, the history should include any thromboembolic events and medications used for treatment. Central nervous system thromboembolic events should be carefully described, along with any residual neurologic deficits. Laboratory studies and preoperative preparations should be tailored to each disorder.

The Former Preterm Infant

When compared with infants born at term, former preterm infants (born at <37 weeks’ gestation) are estimated to be at higher risk of postoperative

apnea and bradycardia after general anesthesia until a postconceptual age of approximately 60 weeks.²⁸ Parents of former preterm infants should be counseled to expect an overnight stay after surgery (pediatricians should check the policy of their local facilities because the exact postconceptual age requiring overnight observation varies slightly from one institution to another). Physical signs in children with sequelae of preterm birth (eg, bronchopulmonary dysplasia, neurologic deficits) should be noted to establish a baseline for comparison and to aid intraoperative planning.

Muscular Diseases

Muscular dystrophies merit special attention because their multisystem effects have profound implications for anesthesia.²⁹ Special approaches to anesthesia, such as the avoidance of exposure to inhaled agents, are often necessary. Young children with hypotonia who do not carry a formal diagnosis should be identified so appropriate precautions can be taken. In many of these cases, mitochondrial inborn errors of metabolism are being considered in the differential diagnosis. In these cases, anesthetic approach and fluid management are different from that for muscular dystrophy; therefore, any relevant data indicating a specific metabolic deficiency are helpful.

Hypertension

Although mild to moderate hypertension does not seem to negatively affect outcome in the perioperative period, 2 issues need to be attended to preoperatively: (1) secondary causes of hypertension need to be identified and corrected before surgical intervention when possible; and (2) antihypertensive medications should be continued through the time of surgery. The exceptions to this rule are the angiotensin-converting enzyme inhibitors, which are generally held

on the day of the procedure.³⁰ The decision to administer these medications should be made with input from the anesthesiologist.

Diabetes Mellitus

For patients with diabetes mellitus, the key perioperative issue is: "how well controlled is the diabetes mellitus?" A patient with poorly controlled diabetes mellitus may need to have elective procedures postponed until blood sugar concentration is controlled.³¹ It is critical to coordinate care with the patient's endocrinologist and anesthesiologist to ensure optimal insulin management during the NPO interval before surgery. Families should be told to expect to arrive especially early on the day of surgery, to allow monitoring of glucose, to adjust insulin administration, and to begin administration of dextrose-containing intravenous fluids.

Morbid Obesity

Morbidly obese patients have potential issues with positioning, airway maintenance, placement of intravenous catheters, and comorbidities, such as obstructive sleep apnea and diabetes mellitus, which raise the risk profile of these patients.³² Baseline height, weight, and BMI should be recorded. If a history of significant sleep disturbance is elicited, consideration should be given to obtaining a sleep study to quantify the degree of obstructive sleep apnea. In general, patients who are morbidly obese would benefit from a consultation with an anesthesiologist and can be counseled that they may have a peripheral intravenous catheter placed before induction of anesthesia.

Patients With Transplanted Organs

Posttransplant patients have invariably undergone many procedures, and this history may result in extreme anxiety surrounding medical interventions. They require special attention to their stress

levels (and possible sedation) preoperatively. Immunomodulatory medications should be continued through the perioperative period, and coordination with the transplant team regarding medication management is helpful.

Inborn Errors of Metabolism

Patients with metabolic disease pose 3 general issues for optimal perioperative management. The first is the effect of the preoperative fast, which may have to be modified (or supplemented with an intravenous glucose infusion). The second issue pertains to the downstream effects of the particular disease, such as seizures, airway involvement, or developmental delay. Finally, the potential adverse effects of intravenous fluids, glucose, and certain medications must be considered. It is helpful for the pediatrician to facilitate early contact between the family, metabolic specialist, and anesthesiologist for careful preoperative planning involving all of these potential problem areas.

Renal Insufficiency/Failure

Three major classes of problems are important perioperatively in patients with renal impairment: electrolyte imbalances, fluid status, and associated medical conditions. Potassium concentrations need to be closely monitored. Hyperkalemia should be noted, and if the potassium concentration is significantly elevated from baseline, it should be treated preoperatively. A history of recent weight gain may signal fluid retention and should be relayed to the anesthesia team. Decreases in exercise tolerance can signal cardiac dysfunction. Underlying causes of renal dysfunction (eg, lupus, metabolic or toxic causes) should be noted for anesthesia providers.

Oncologic Diseases

There are 2 important considerations for patients who have or have had

oncologic diseases. First, patients with a mediastinal mass (most often with a new lymphoma diagnosis) are at risk for lethal airway or great vessel compression on induction of anesthesia.³³ Important signs include the inability to lie supine, dyspnea on exertion, plethora of head and neck, and biphasic stridor. Second, treatments for oncologic diseases can have profound effects on the overall perioperative management. Exposure to chemotherapies, such as bleomycin or doxorubicin, can result in long-term effects, such as pulmonary fibrosis and cardiomyopathy.^{34,35} Radiation treatments can cause fibrosis in multiple tissues, which can result in limited mouth opening and neck movement and can worsen pulmonary fibrosis.³⁶ Hematologic and metabolic perturbations are common during oncologic therapy and should be carefully monitored before surgery. Data regarding any of these factors are important to include with the preoperative evaluation.

Developmental Delay/Autism

The perioperative environment can be confusing and scary for any child, perhaps more so for those with cognitive delays. In addition, evaluation of postoperative pain can be difficult, and parents should be questioned about specific pain behaviors in their child. Difficulties in sensory processing and the social interaction often make the perioperative period difficult for children with autism spectrum disorders. Education of the family and child on the process of anesthesia and surgery is generally helpful. Parents should be queried for advice on how a particular child can be best approached by the

perioperative care team.³⁷ Information on “triggers” for aggressive behavior or comfort items should be communicated in a preoperative note.

Do-Not-Resuscitate Orders for Patients in the OR

The American Academy of Pediatrics, the American Society of Anesthesiologists, and the American College of Surgeons have statements on issues related to do-not-resuscitate (DNR) status during operative interventions.^{38,39} DNR orders will be reviewed with patients and families in light of the expected effects of surgery (eg, blood loss) and anesthesia (eg, intubation, cardiac effects of certain drugs). The family and surgical and anesthesia teams will decide on the best option for managing DNR status, which may include modification, suspension, or continuation for the perioperative period.⁴⁰ Patients need to know that such a discussion will occur before entering the OR.

Religious Considerations

For procedures such as spinal fusions or cranial vault reconstructions, blood transfusions are common. Jehovah's Witness families should meet with the anesthesiologist to review the options for handling hematologic issues. The legal and ethical issues are complex.⁴¹ In the event of life-threatening blood loss, many states allow blood transfusion in minors. The family and anesthesia team should discuss the implications of the law in the state in which surgery will be performed. The family can be reassured that all possible measures to avoid transfusion will be taken. Other religious practice

considerations include requirements for wearing specific clothing, charms, or covering the head. Removal of these items may or may not be required for anesthesia or surgery, and the pediatrician should counsel the family to discuss options with the anesthesia team.

CONCLUSIONS

Pediatricians are in a unique position to help prepare children and their families for surgery and help the perioperative team optimize care. Communication about conditions related to increased risk in the OR and aiding the family to advocate for their child in a stressful situation are valuable contributions to the preoperative preparation of the pediatric patient.

CLINICAL REPORT

Physician Health and Wellness

abstract

FREE

Physician health and wellness is a critical issue gaining national attention because of the high prevalence of physician burnout. Pediatricians and pediatric trainees experience burnout at levels equivalent to other medical specialties, highlighting a need for more effective efforts to promote health and well-being in the pediatric community. This report will provide an overview of physician burnout, an update on work in the field of preventive physician health and wellness, and a discussion of emerging initiatives that have potential to promote health at all levels of pediatric training.

Pediatricians are uniquely positioned to lead this movement nationally, in part because of the emphasis placed on wellness in the Pediatric Milestone Project, a joint collaboration between the Accreditation Council for Graduate Medical Education and the American Board of Pediatrics. Updated core competencies calling for a balanced approach to health, including focus on nutrition, exercise, mindfulness, and effective stress management, signal a paradigm shift and send the message that it is time for pediatricians to cultivate a culture of wellness better aligned with their responsibilities as role models and congruent with advances in pediatric training.

Rather than reviewing programs in place to address substance abuse and other serious conditions in distressed physicians, this article focuses on forward progress in the field, with an emphasis on the need for prevention and anticipation of predictable stressors related to burnout in medical training and practice. Examples of positive progress and several programs designed to promote physician health and wellness are reviewed. Areas where more research is needed are highlighted. *Pediatrics* 2014;134:830–835

INTRODUCTION

Physician health and wellness is an issue garnering national interest because of the high prevalence of burnout in medical practitioners and trainees. Burnout takes a steep toll on physicians and has negative effects on patients and health care systems.¹ Research advances detailing the detrimental effects of chronic stress, including impaired immune function, inflammation, elevation of cardiovascular risk factors, and depression,^{2–9} are directly relevant to pediatric practitioners and create a need for organized efforts to address physician health and well-being in the pediatric community. The purpose of this report is to provide an update on the issue of physician health and wellness with regard to how they relate to pediatricians. Rather than reviewing programs already in place to address substance abuse and other serious conditions in distressed

physicians, this report focuses on forward progress in the field, with an emphasis on the need for prevention and anticipation of predictable stressors related to burnout in medical training and practice. Although specific recommendations are beyond the parameters of this report, examples of positive progress and national programs to promote physician health and wellness will be reviewed.

BURNOUT: THE ANTITHESIS OF WELLNESS

Physician burnout is commonly assessed using the Maslach Burnout Inventory, which uses 3 general scales to measure characteristics of burnout. These include emotional exhaustion, depersonalization, and sense of personal accomplishment.^{10,11} Burnout is higher in physicians than in the general population and peaks during training¹² as well as mid-career.¹³

Prevalence of burnout in pediatrics mirrors rates in other medical specialties (30%–50%),^{14,15} with higher rates documented in specialties such as hematology-oncology, neonatal and intensive care, and pediatric surgery.^{16–19} In a periodic survey of American Academy of Pediatrics (AAP) members ($n = 1616$; response, 63%), 22% of surveyed physicians agreed they were currently experiencing burnout, and 45% agreed they had experienced burnout in the past.²⁰ Burnout has also been documented in pediatric trainees. A longitudinal prospective study of pediatric residents at Stanford University Lucille Packard Children's Hospital showed a significant increase in all burnout characteristics (emotional exhaustion, depersonalization, and sense of personal accomplishment) by February of their internship year, reaching prevalences of 24% to 46% (depending on burnout criteria used). High burnout rates persisted throughout residency training.²¹ Multiple studies have documented high levels of burnout in medical and premedical students.^{22–25}

Drivers of physician burnout are multifactorial and have been widely reported in the literature, and include an expectation of unrealistic endurance, time pressure, excessive work hours, threat of malpractice suits, difficult patients, coping with death, unprocessed grief, sleep deprivation, and unsupportive work environments. Professional demands coupled with personal stressors, such as financial worries, limited free time, isolation, uncertainty, a culture of silence, and a lack of effective stress management skills, further compound burnout risk.²⁶ Even reduction in resident duty hours, instituted by the Accreditation Council for Graduate Medical Education (ACGME) in 2003 in the United States, has had the unintended consequence of increased attending physician workload and decreased teaching time while increasing burnout and job dissatisfaction.²⁷

Ironically, many of the character traits valued in pediatricians, such as compassion, altruism, and perfectionism, also predispose to burnout when clinicians are pushed to mental or physical extremes. Although the warning signs and symptoms may be subtle, burnout is often accompanied by anxiety or depression. Suicidal ideation and, tragically, completed suicide are not uncommon. It is a sobering fact that an estimated 300 to 400 physicians in the United States commit suicide annually. Women physicians are at highest risk, with an estimated relative risk ratio of 2.7 for suicide in relation to the general female population,^{28–30} cause for heightened awareness in pediatrics, a field in which women now make up the majority of trainees.³¹

STIGMA AND SANCTIONS

Recognition of burnout in one's colleagues or in oneself raises challenging questions, especially in light of the relative lack of available resources and the lingering stigma of disciplinary sanctions. In fact, it was only after a 1973 "landmark" policy paper in the *Journal of the*

*American Medical Association*³² linking addictive behavior and other mental health issues in physicians with the term "sick" rather than "disciplinary problems" that The Federation for State Physician Health Programs was developed. The *Journal of the American Medical Association* article offered a rare public glimpse into the closed medical community and acted as a powerful catalyst for change. By 1980, 51 of the 54 medical societies of all states and jurisdictions had authorized or implemented impaired physician programs, mandated to identify, treat, and rehabilitate physicians struggling with burnout-related drug and alcohol addiction.³³ Although these programs have benefitted many physicians, a culture of stoicism still permeates the practice of medicine, slowing progress in the push for a more open dialogue about physician health and wellness.

REDUCING BURNOUT: A SHIFT TO PREVENTION

Recognized steps to reduce physician burnout include: providing physicians and trainees a greater sense of control, absence of role conflict, a sense of fair treatment, positive social support, appropriate financial, institutional, and social rewards, and proper alignment between the values of an individual and his or her workplace.¹⁰

The need for systems-based, rather than individual efforts, to reduce burnout is reflected in 2 important initiatives. The first is the 2009 Joint Commission guidelines mandate that medical staff "...implement a process to identify and manage matters of individual health for licensed independent practitioners which is separate from actions taken for disciplinary purposes."³⁴ The second, specific to the field of pediatrics, is the Pediatric Milestone Project, a major collaborative effort between the ACGME and the American Board of Pediatrics tasked with updating core competencies

in pediatric training. Language in the newly developed Personal and Professional Development competencies speaks directly to cultivation of skills that address burnout prevention and finally shift the perspective toward preventive wellness. For example, the Personal and Professional Development competency identifies a need for regular physical activity, healthy nutrition, and supportive social connections as well as development of skills in stress management, self-awareness, and the ability to engage in help-seeking behaviors to maintain health and well-being. Cultivation of empathy, humanism, and compassion are identified in the new Professionalism competency.^{35,36}

The challenge will be in implementation and measurement of these new competencies, which will require the full engagement of pediatric mentors who place a high value on physician well-being and recognize the importance of preventing burnout at all stages of pediatric training and practice.

PHYSICIAN HEALTH AND WELLNESS IN THE AAP

The mission of the Special Interest Group on Physician Health and Wellness is to raise awareness throughout every level of the AAP and to develop educational programming and resources on physician health and wellness that are accessible to all members. Stewardship of the Special Interest Group transitioned to the Section on Integrative Medicine in 2011. In part, this occurred because a primary educational focus of the Section on Integrative Medicine is preventive health, including core topics such as nutrition, physical activity, healthy sleep, stress management, and self-regulation skills, which provide a useful blueprint for preventive physician health.

THE COMPONENTS OF WELLNESS

Hundreds of studies have confirmed the high prevalence of burnout, yet relatively

few have examined or quantified the characteristics of physician wellness. Some studies have demonstrated that issues such as work-life balance, social and family support, adequate rest, and regular physical activity correlate with career satisfaction, improved sense of well-being, increased empathy, and decreased burnout.^{37,38} As opposed to physicians who neglect their health,³⁹ physicians with healthy lifestyle habits have been perceived as more credible and motivating to their patients and the residents under their supervision.^{40–42} It has been shown that wellness behaviors in physicians are additive; therefore, individuals should be encouraged to adopt a variety of approaches to best suit their individual needs.⁴³

Comparison of 2 AAP periodic surveys (Periodic Survey No. 54 in 2003 and Survey No. 81 in 2012) examined work hours, presence of minor children at home, perceived stress of balancing work/home responsibilities, and satisfaction with amount of time available to spend in several personal activities. In 2012 pediatricians reported less stress balancing home and work than in 2003. This reduction in perceived stress was correlated with reduced work hours and not having minor children at home. In 2012, pediatricians reported higher satisfaction with time to spend with spouse/partner, friends, hobbies, community activities, and spiritual needs.^{44,45}

EXAMPLES OF PROGRESS: CREATING A NATIONAL CULTURE OF PHYSICIAN WELLNESS

Although some programs have been established after tragic losses of colleagues, such as the comprehensive Suicide Prevention and Depression Awareness Program at the University of California, San Diego School of Medicine,²⁸ other residency programs and medical schools in the United States have taken the opportunity to proactively institute comprehensive wellness

programs. Support from administrative faculty leaders has been identified as integral to most of these programs. Some characteristics of these programs include creation of a wellness mission statement for the organization; identification of key components for developing and maintaining wellness; measuring and tracking burnout in residents and faculty; creation of a lecture series on wellness topics; resident support groups early education about stress management; cultivation of resilience; development of a confidential fast-track referral source for mental health services; annual resident retreats focused on health and wellness; raising awareness of the correlation between resident wellness and faculty wellness; online curriculum on self-care and wellness; and selection of primary care physicians unrelated to the training program available to residents for ongoing health care. Example programs include:

- Learner Advocacy and Wellness at the University of Alberta, Edmonton, Canada⁴⁶
- Physician Well-Being Program, William Beaumont Hospitals, Troy Family Medicine Residency Program, Detroit, Michigan¹⁴
- Vanderbilt Wellness Program, Vanderbilt School of Medicine, Nashville, Tennessee⁴⁷
- Resiliency and Wellness Education Program, University of California, San Diego Department of Emergency Medicine⁴⁸
- Integrative Medicine in Residency Program, University of Arizona⁴⁹ and the Pediatric Integrative Medicine in Residency Program, University of Arizona

Collectively, these programs demonstrate the power of developing an organized plan to promote wellness in their physician communities and highlight the importance of institutional efforts to alter the status quo.

NEW FRONTIERS OF WELLNESS: MINDFULNESS IN MEDICINE

Recognition of the detrimental health effects of chronic stress has catalyzed the search for better approaches to stress reduction in physicians. Although numerous lifestyle approaches are under consideration, research on the use of mindfulness in the medical setting currently has substantial supporting evidence. This can be traced back to the early work of Jon Kabat-Zinn, PhD, who has described mindfulness as “conscious, moment-to-moment awareness, cultivated by systematically paying attention on purpose in a particular way.”⁵⁰

Mindfulness as a self-regulation tool aligns with the new ACGME core competencies and has been used by physicians in various formats. Some examples include mindful communication programs that involve meditation, self-awareness exercises, processing of clinical experiences, and appreciative interviews. Reduction in burnout measures, such as depersonalization and emotional exhaustion, and improvements in mindfulness, empathy, and feeling of personal accomplishment were observed.^{51–53} Use of mindfulness has also resulted in significant improvement in burnout scores and mental well-being when offered on a recurring basis as a continuing medical education course,⁵⁴ or as online modules for residents and faculty.^{55,56}

The effect of education in mindful communication has been examined in physicians in a structured training program, which produced 4 main themes of feedback from participants: (1) participants felt a decrease in sense of personal isolation; (2) mindfulness training helped physicians listen more deeply and attend to the patient's concerns more effectively; (3) adaptive reserve was increased; and (4) participants experienced a feeling of greater self-awareness that proved, in many cases,

to be transformative.^{57,58} Mindfulness may also support more thoughtful decision-making and can enhance empathic communication. Precedent in the use of mindfulness exists in law and business, where it is used to reduce reactivity in stressful situations. The use of mindfulness and guided imagery is also gaining acceptance in the military to reduce stress and enhance performance.^{59,60}

One of the few available randomized controlled clinical trials in physician burnout intervention demonstrated substantial decrease of rates of depersonalization, emotional exhaustion, and overall burnout in the treatment group and resulted in improved sense of meaning and engagement in work in 74 practicing internal medicine physicians who attended 9 months of biweekly facilitated discussion groups that incorporated elements of mindfulness, reflection, shared experience, and small group learning.¹⁵ More research is needed to identify programs that will best serve the needs of pediatricians at various stages of training and practice.

CONCLUSIONS

Physician health and wellness is a complex topic, relevant to pediatricians at all stages of training. Advances in our understanding of the harmful effects of chronic stress and consequent shifts in ACGME core competencies prioritizing pediatric resident wellness create a need for programs that will help practicing pediatricians not only keep pace but also become leaders and role models in shaping a healthier culture of pediatric practice.

A primary purpose of this clinical report is to shift the focus from burnout treatment to preventive physician health and wellness and identify factors that will increase career satisfaction and longevity, including promotion of a balanced lifestyle that includes physical

activity, healthy nutrition, restorative sleep, supportive relationships, and effective stress management skills. The Section on Integrative Medicine hopes this clinical report serves as a catalyst for more open discussion of physician health and wellness within the AAP and will lead to the development of meaningful programs with the potential to benefit all AAP members.

Pediatricians play a key role in advancing child health research to best attain and improve the physical, mental, and social health and well-being of all infants, children, adolescents, and young adults. Child health presents unique issues that require investigators who specialize in pediatric research. In addition, the scope of the pediatric research enterprise is transdisciplinary and includes the full spectrum of basic science, translational, community-based, health services, and child health policy research. Although most pediatricians do not directly engage in research, knowledge of research methodologies and approaches promotes critical evaluation of scientific literature, the practice of evidence-based medicine, and advocacy for evidence-based child health policy. This statement includes specific recommendations to promote further research education and support at all levels of pediatric training, from premedical to continuing medical education, as well as recommendations to increase support and mentorship for research activities. Pediatric research is crucial to the American Academy of Pediatrics' goal of improving the health of all children. The American Academy of Pediatrics continues to promote and encourage efforts to facilitate the creation of new knowledge and ways to reduce barriers experienced by trainees, practitioners, and academic faculty pursuing research. *Pediatrics* 2014;133:943–949

INTRODUCTION

The goal of the American Academy of Pediatrics is the attainment of the optimal physical, mental, and social health and well-being of all infants, children, adolescents, and young adults. To achieve this vision, pediatrics, as a field, must continually add to the current knowledge about how to best care for children through pediatric research. Research is broadly defined as the “systematic investigation, including research development, testing and evaluation, designed to develop or contribute to generalizable knowledge.”¹ For the purposes of this statement, the term “child” health research refers to research focused on infants, children, adolescents, and young adults.

Child Health Research Is a Unique Field

Child health presents unique issues that require investigators who specialize in pediatric research. For example, childhood affects an

individual's long-term health trajectory and future adult outcomes, as many "adult" diseases have been shown to have their roots in childhood.²⁻⁴ The long-term effects of childhood interventions may be difficult to discern, and an intervention may take many years until any benefit is noted. Some cases, such as early child development interventions, can yield higher returns as a preventive measure compared with remedial services later in life⁵; however, it can be challenging to assess these potential long-term benefits with traditional approaches. Child health research also is characterized by the development and refinement of approaches to document long-term impact of early interventions.

The acceleration of racial and ethnic diversity in the United States is most pronounced in the pediatric population. Children now represent the most racially and ethnically diverse age group in the United States. As of 2011, most infants born in the United States had parents of ethnic minority groups.^{6,7} As a result, for those involved in child health care, it is crucial to develop and assess interventions to ensure they are culturally and linguistically, as well as developmentally, appropriate.^{8,9}

Compared with adults, children and adolescents have fewer common chronic conditions (eg, obesity, asthma, attention-deficit/hyperactivity disorder) but also have a wide plethora of rare diseases manifest in a very small percentage of children.^{10,11} It is challenging to develop research programs to study and create new treatments for rare and orphan disorders. This skewed epidemiology influences decisions regarding the allocation of resources of biomedical research.¹² For a variety of factors, medical advances are often developed for and tested initially in adults, frequently leaving pediatric

practitioners with little or no evidence-based guidance on appropriate use in children.¹³ The discovery, development, proper evidence-based evaluation, and translation of pediatric medical advances are vitally important to the health and well-being of the world's infants, children, adolescents, and young adults.

Finally, children are dependent on parents or adult guardians. This issue adds further ethical considerations in the conduct of pediatric research, such as the need to obtain parental consent and child or adolescent assent.^{14,15}

Child Health Research Is Broad in Scope

The scope of the pediatric research enterprise must also include the full spectrum of basic science, clinical, community-based, health policy, and health services research for appropriate translation into pediatric clinical practice. The Institute of Medicine¹² describes this translational research as the "transfer of new understandings of disease mechanisms gained in the laboratory into the development of new methods," as well as the "translation of the results of clinical studies into everyday clinical practice and health decision making." As a result, the research enterprise requires skills that include molecular and basic science laboratory skills; the conduct of randomized controlled trials and observational studies; and skills in designing, implementing, and evaluating interventions in everyday settings and/or analyzing the implications of health policies on child health outcomes.¹⁶ Furthermore, the movement of new knowledge is bidirectional, as insights gained in clinical settings inform inquiries in the basic sciences.

In the past, members of research teams focusing on pediatric issues had similar training; however, complex

clinical and societal issues require complementary sets of theoretical backgrounds and skills. Current issues in pediatric health are influenced by multiple factors (eg, genetic, environmental, political, social). Approaches to address these issues require medical research that involves a multitude of disciplines (eg, genetics, bioinformatics, epidemiology, sociology, health behavior and health education, health policy analysis, economics).¹⁷ In addition, research may need to acknowledge different theoretical models and incorporate diverse skills and methodologies used in other fields. Pediatric investigators may benefit from additional formal coursework, secondary degrees (eg, Master of Public Health, Doctor of Philosophy), research fellowships, and/or access to collaborators and faculty from other disciplines.

Working with families of patients in community settings through community-based participatory research adds a valuable dimension to health outside the treatment setting. Such research explores ways in which patient, family, and community priorities and settings may support or hinder complex disease management. Empowering the community as an equal partner in research offers promise for real change in the health of the population.¹⁸

The Importance of Pediatric Research Education for All Pediatricians

Although most pediatricians select careers primarily as practitioners, not research investigators,¹⁹ appropriate exposure to and an appreciation of research methodologies promotes skills and competencies for the critical evaluation of scientific literature and the practice of evidence-based medicine. These skills are closely interconnected to core competencies emphasized in pediatric education,

especially practice-based learning and improvement.²⁰ In addition, this training fosters a culture of deliberate and critical evaluation in pediatric clinical practice. It is not possible to practice evidence-based medicine without understanding the strengths and limitations of how the evidence was gathered and analyzed.²¹

In addition, a current gap is the paucity of child health research conducted in office-based settings, as opposed to highly specialized academic centers.²² Early exposure to research may increase the likelihood of practitioner involvement in practice-based research networks (PBRNs), which generate new knowledge that may be more generalizable to everyday practice.²³ Evidence-based practice is not possible without practice-based evidence. The increasing use of electronic health records in primary care settings and new maintenance-of-certification requirements create new opportunities and potential challenges for incorporating research in office settings. The generation of applicable, practice-based evidence is dependent on the active contributions of practicing pediatricians who understand and value pediatric research.

Current Threats to the Pediatric Research Enterprise

It is critical for pediatric research to continue to attract talented young trainees. Already, overall educational cost in comparison with potential future income is less favorable for physicians compared with many other professionals.²⁴ This situation is exacerbated for physician scientists, because they have more years of training, increased opportunity costs, and lower average salaries as academic pediatricians.²⁵ Over the past 3 decades, the amount of medical education debt has been increasing. In

2012, 86% of medical students obtained educational loans, with a resulting median individual medical student debt level of \$170 000.²⁶

The combination of increasing debt and lower expected earnings may discourage trainees from pursuing research careers.²⁷ In a survey of current pediatric subspecialist fellows, more than half indicated that, given the option, they would have chosen a shorter fellowship without a research requirement.²⁸ This sentiment was also noted by approximately 40% of junior faculty surveyed who had just completed fellowship training.²⁹ High levels of debt may contribute to a reluctance of young pediatricians to pursue a career in pediatric academic research and threaten the pipeline of future discoveries to benefit children.

In the past decade, extramural funding for research has become more competitive.³⁰ Pediatric funding from the National Institutes of Health (NIH) has mirrored the overall general NIH funding levels. As the budget for NIH has increased from fiscal year 1998 to fiscal year 2003 by 13.4%, pediatric funding increased by 11.5%; however, from fiscal year 2004 to fiscal year 2009, NIH appropriations increased by only 1.3%, with a corresponding change in pediatrics of only 0.3%. Accounting for inflation, the changes in the most recent period represent a negative change for pediatric research funding. Overall, for the individual pediatric investigator, this change represents few grants and fewer dollars per grant.³¹ There are fewer resources available to obtain a career development award and fewer resources for the transition to independent funding. In 2011, the average age of an investigator receiving an initial R01 (investigator-initiated grant) was 44 years for a Doctor of Medicine–Doctor of Philosophy

(MD-PhD) and 45 years for a Doctor of Medicine (MD).³² The decreased availability of research funding from NIH is a considerable barrier to young physician investigators.

Institutions may have a variety of expectations for faculty physician-researchers, such as teaching, clinical care, administration, and research.^{33,34} Given the increasingly competitive nature of securing extramural funding and requirements for clinical productivity, a career that attempts to balance research and clinical care is extremely challenging. Institutions need to invest significant resources (eg, senior faculty mentorship, space, technical support, supplies) as well as specified research time for junior faculty, which is often underestimated. This research time needs to be valued similarly to clinical, teaching, and administrative responsibilities.³⁵ In addition, it is important for clinical work to be synergistic with an investigator's research focus. Finally, extramural funding may not cover all project and infrastructure costs. As a result, institutional or medical center support may be necessary to support research faculty.

Diversity in the pediatric research workforce is increasingly important to help address the health care issues of a population that continues to grow more diverse.³⁶ Similar to the general pediatric workforce, there is a lack of diversity in academic pediatrics as well as among academic pediatric investigators.^{37–39} A lack of mentoring and support has been cited as one barrier to racial/ethnic minority application and competition for NIH research funding.⁴⁰ Examples of programs attempting to address this issue are the Academic Pediatric Association New Century Scholars Program and the Robert Wood Johnson

Foundation Harold Amos Medical Faculty Development Program.

RECOMMENDATIONS

The history of pediatric contributions to medical research is rich.⁴¹ These contributions are dependent on how pediatrics, as a field, promotes education, mentorship, and support for discovery and research throughout the career spectrum. As a result, education in research methodology should be provided, from medical school for pediatricians-in-training to continuing medical education for practicing pediatricians. The American Academy of Pediatrics continues to promote and encourage efforts to facilitate the creation of new knowledge and ways to reduce barriers experienced by trainees, practitioners, and academic faculty pursuing research.

Research Training Before Medical School

- Research training must begin early, ideally as a component of premedical course work.⁴²
- Early “pipeline” programs also may be helpful in attracting students of underrepresented minorities and lower socioeconomic status into the field of medicine and medical research. The pediatric research community should promote, encourage, and mentor high school and college students to develop career interests in medical research.

Research Training in Medical School

- Medical schools should provide a curriculum for health research.⁴³ This curriculum should encourage lifelong learning and develop trainee competencies in critically reviewing scientific literature. Fac-

ulty from pediatric departments should be encouraged to participate in the design and teaching of such curricula.

- Medical schools should consider recommending or requiring hypothesis-driven thesis projects for their students and should support dedicated time (for students and faculty), necessary resources, and faculty mentorship. Electives in research for credit (such as during the summer after the first and second years of medical school) or an additional year for fellowship for medical students to permit completion of a research project are additional options that can be established to support early development of the skills needed to conduct quality research.
- Medical student curriculum should include the issues of designing, conducting, and interpreting health research. The curriculum also should include the ethical dimensions of research, including informed consent, the role of institutional review boards, protection of research subjects, conflict of interest, and patient privacy, which are relevant to a research curriculum for physicians at any level of training or practice.

Research Training in Pediatric Residency Programs

- Consistent with the requirements of the Accreditation Council for Graduate Medical Education, an evidence-based medicine curriculum that can be integrated into a conference schedule should be developed for pediatric residents. The primary goal of this curriculum is to train pediatric resident competencies to evaluate and use medical literature as well as understand basic scientific methods, research design fundamentals, core

statistical principles, and the means to conduct critical literature reviews.

- Pediatric residency programs should promote research opportunities and encourage trainees to participate in a research project during their residency. Specified time, necessary resources, and faculty advisors are critical components in developing a research career or becoming involved in clinical research as a pediatric practitioner. These components should be readily available at all levels of pediatric training.

Research Training in Pediatric Fellowship Programs

- Fellowship programs should include advanced formal course work in research methodology that covers the widest possible spectrum of child health research. A research methodology curriculum for all fellowships in pediatrics should be developed that will outline the minimal core knowledge and skills expected of all child health researchers across subspecialties and general pediatrics. A core research methodology curriculum that is transdisciplinary and broad in scope can facilitate collaboration and potentially improve the quality and practical relevance of research conducted.
- The mentored-research experience is often cited as the key aspect of fellowship training.³³ Programs should assign all fellows to experienced faculty research preceptors with whom to work. To support mentorship, federal training grants should provide faculty mentor salary support in addition to trainee stipends. Institutions applying for fellowship training support should describe their plans for mentorship activities.

Research Training and Support for Junior Faculty

- Training and career development in a successful research career does not cease at the end of fellowship training. Junior faculty members require institutional support and mentoring to develop successful academic careers. Junior faculty members should develop individual career development plans and have such plans reviewed annually with their administrative and research mentors.
- Programs to identify, mentor, and link new investigators to a cohort of peers can help improve the likelihood of academic success.⁴⁴

Research Training Within Continuing Medical Education

- For continuing education of practitioners and academic faculty, educational institutions and professional organizations should establish programs in which intensive, brief training in research methodology or critical review of the scientific literature is provided.

Research and Pediatric Clinical Care

- Opportunities for pediatric practitioners to participate in research activities should be expanded through local and national PBRNs. Examples of national PBRNs include networks for outpatient settings (Pediatric Research in Office Settings), emergency department settings (the Pediatric Emergency Care Applied Research Network), and inpatient settings (Pediatric Research in Inpatient Settings), among others.
- PBRNs should be further promoted and expanded to reach practitioners previously underrepresented in these activities, especially those

who care for minority and underserved populations.⁴⁵

- To ensure that ongoing clinical experience can be harnessed to benefit future pediatric patients, incentives to support clinical research should be aligned with clinical care incentives.⁴⁶ Each clinical encounter represents a potential opportunity to contribute to primary data collection, quality improvement, or future secondary data analyses. An example of the successful integration of clinical care and clinical pediatric research is the Children's Oncology Group, which has improved the survival rate for childhood cancer through systematic, hypothesis-driven clinical research over the past 50 years.⁴⁷
 - Programs that help educate patients and families about the role, importance, and proper conduct of pediatric research should be promoted to help support the pediatric research enterprise.⁴⁸
- ### Loan Forgiveness and Research Support
- Programs that provide federal support for repayment of educational debt for physicians pursuing careers in child health research are important and should be continued to help encourage trainees to pursue careers in the field.⁴⁹
 - Secure and sustained resources need to be identified to cover costs of research education at all levels, including subsidizing faculty time, space, supplies, and equipment.
 - Professional organizations providing oversight for training of pediatricians and major federal funders of child health research (eg, NIH, Health Resources and Services Administration, and Agency for

Healthcare Research and Quality) should collect data to monitor the quality of pediatric research training, the number of pediatric researchers completing training and their productivity as researchers, and the level of support for child health research activities to ensure that there is ongoing progress in these areas.

- Junior faculty research success is dependent on outstanding mentorship from senior faculty. Academic institutions should support innovative programs to develop, cultivate, and recognize outstanding faculty research mentorship.⁵⁰

CLINICAL REPORT

Psychosocial Support for Youth Living With HIV

abstract

FREE

This clinical report provides guidance for the pediatrician in addressing the psychosocial needs of adolescents and young adults living with HIV, which can improve linkage to care and adherence to life-saving antiretroviral (ARV) therapy. Recent national case surveillance data for youth (defined here as adolescents and young adults 13 to 24 years of age) revealed that the burden of HIV/AIDS fell most heavily and disproportionately on African American youth, particularly males having sex with males. To effectively increase linkage to care and sustain adherence to therapy, interventions should address the immediate drivers of ARV compliance and also address factors that provide broader social and structural support for HIV-infected adolescents and young adults. Interventions should address psychosocial development, including lack of future orientation, inadequate educational attainment and limited health literacy, failure to focus on the long-term consequences of near-term risk behaviors, and coping ability. Associated challenges are closely linked to the structural environment. Individual case management is essential to linkage to and retention in care, ARV adherence, and management of associated comorbidities. Integrating these skills into pediatric and adolescent HIV practice in a medical home setting is critical, given the alarming increase in new HIV infections in youth in the United States. *Pediatrics* 2014;133:558–562

BACKGROUND

The US government released a National Strategy for HIV/AIDS in 2010, in which 3 common goals were stated: (1) to reduce the number of individuals who become HIV infected; (2) to increase access to care and improve health outcomes in HIV-infected individuals; and (3) to reduce HIV-related health disparities.¹ These goals reflect significant progress in treatment of HIV infection with effective combination antiretroviral therapy (cART). This approach requires an ever-vigilant approach to long-term antiretroviral (ARV) adherence ($\geq 95\%$) for optimal virologic suppression and to offset the emergence of drug-resistant HIV so that future treatment options remain viable. Unfortunately many HIV-positive youth are not consistently linked into or retained in care. Youth who miss clinic appointments are more likely to develop life-threatening opportunistic infections. Poor adherence to cART is also associated with increased secondary HIV transmission.²

Epidemiology

HIV-infected youth consist of 2 distinct populations: those who acquired HIV infection perinatally and those infected horizontally either by transfusion of blood products or by risk behaviors, including sexual activity and intravenous drug use. As of 2010, there were an estimated 10 797 perinatally HIV-infected people in the United States and dependent areas, and 76% of those affected were ≥ 13 years of age at the time of the analysis.³ Recent surveillance data from 2009 and 2010 reveal that youth account for 26% of all new HIV infections in the United States. Nearly 75% and 46% of the 12 200 new HIV infections in youth were attributable to males having sex with males and African American adolescents and young adults, respectively.⁴ Stigma, discrimination,⁵ infrequent condom use, alcohol and drug use, and having sex with older partners⁶ contributed to an even higher risk for acquiring HIV infection, disproportionately affecting minority youth residing in the south and the north-eastern United States. An estimated 60% of individuals were unaware of their underlying HIV infection.⁷

Challenges to ARV Adherence Among HIV-Infected Youth in the United States

Poor adherence to ARV therapy has been documented for both perinatally and horizontally HIV-infected youth. Many children infected with HIV perinatally have survived into their second or third decade of life with cART. However, during adolescence a number of psychological and social factors influence decision-making and create challenges for effective ARV adherence. A retrospective multicenter study of adolescents who acquired HIV perinatally reported that adolescents and young adults had the highest risk for resistance to available ARVs secondary to poor drug adherence.^{8,9} Similar

findings among adolescents and young adults who acquired HIV horizontally are reported, with as few as 24% in 1 study achieving virologic suppression at 3 years after initiation of cART.¹⁰ Such observations reinforce the need to design, implement, and evaluate strategies to increase and sustain adherence to therapy in this group. Interventions must factor the adolescents' stage of development, education level, health literacy and coping ability, and structural environment.¹¹ Factors that have been implicated in poor levels of adherence and ARV efficacy include poverty, inadequate food access,^{12,13} unstable housing,⁸ limited educational attainment, lack of stable employment, substance abuse, denial, stigma, homophobia, and discrimination.¹⁴

HIV Disclosure to Perinatally HIV-Infected Youth

As perinatally HIV-infected children approach adolescence, disclosure of their serostatus becomes essential for personal health maintenance and secondary HIV prevention. The first longitudinal study to examine the impact of disclosure of HIV status on health-related quality of life outcomes documented a median age at disclosure of 11 years. There were no significant changes over time in general health perception, psychological status, physical functioning, social/role functioning, or health care use domains. There was also no significant difference between time trends in quality of life scores before and after disclosure of HIV status, suggesting that diagnostic disclosure to children should not be delayed for fear of a negative impact on quality of life.¹⁵ Disclosure prior to sexual activity is also a public health issue affecting secondary HIV transmission.

Stigma and Disclosure in Horizontally HIV-Infected Youth

Horizontally HIV-infected youth have historically experienced rejection,

violence, and discrimination following disclosure of their HIV status. These experiences reflect prevalent societal stigma toward individuals who have acquired HIV through perceived risk behavior. The detrimental effect of HIV stigma on youth is often reported as more significant than the disease itself⁹ and negatively impacts ARV adherence. In one study, individuals who have HIV who reported high levels of HIV stigma were 3 times more likely to report problems with adherence.⁸ In contrast, when youth reported high levels of satisfaction with health care providers, this ameliorated the negative impact of stigma on adherence to treatment.¹⁶

Children and Youth Who Are in Foster Care or Homeless

Children who have HIV infection are often placed in foster care. Provision of medical services, including hospitalization, can be initially complicated by limited acquisition and communication of medical information. Eliminating barriers to sharing confidential information between medical providers, mental health case managers, and the foster care agency can improve care of the child or adolescent living with HIV.¹⁷ Institutional confidentiality and privacy policies guiding the care of HIV-infected youth should be developed.¹⁸ Samples of confidentiality policies can be found in *Bright Futures*.¹⁹ A complete medical history may be unavailable at the initial visit, and physicians must be prepared to document the circumstances surrounding the unavailability of previous medical records and provide service with limited knowledge of the youth's family, past medical or ARV history, or immunization status.²⁰

Studies indicate that youth aging out of foster care at 18 years of age and those who are lesbian, gay, bisexual, and transgender (LGBT) are especially susceptible to homelessness.²¹ The former, particularly minority youth,

have limited experience in independent living and lack the financial and social supports required to become independent.^{22,23} Many are at increased risk for sexual victimization, school dropout, substance abuse, and mental health comorbidities. Homeless adolescents and young adults frequently engage in prostitution in exchange for money, food, or shelter. The literature estimates that nightly in the United States, homeless youth can number between 1.6 and 2 million, including those living in shelters, on the streets, or in other temporary accommodations. Significantly, LGBT youth account for 20% to 40% of all homeless youth in the United States^{24–26} and are 6 to 12 times more likely to become HIV infected than other youth.²⁷ Homeless youth are 7 times as likely to die from AIDS and 16 times as likely to have HIV infection diagnosed as the general youth population.²⁶ These youth experience high rates of trauma and abuse before and during their experience of homelessness. Violence is reported in many forms, including physical (50%–82%), sexual (26%–39%), and family abuse (50%).²⁸

Acceptance of an HIV Diagnosis and Self-Disclosure to Others

Studies have revealed that youth who have chronic and/or terminal illness experience similar difficulty adjusting to their diagnosis, predominantly with medical management.^{29–32} However, HIV-infected youth have the unique difficulty of also living with stigma, which can interfere with their ability to adjust and cope.^{33,34} Significant stressors include acceptance of their diagnosis and rejection by others following disclosure.³⁵ Many fail to keep their medical appointments and present much later with opportunistic infections.

Schooling

Graduating from school is a major milestone for all youth. Youth living

with HIV infection are most concerned about disclosure to peers causing HIV stigmatization and adversely impacting social functioning. Youth living with HIV infection report changing grades after being given their diagnosis, with some ultimately dropping out of school. Like many youth who have chronic disease, HIV-infected youth in school have the added stress of skipping classes for medical appointments, which can negatively affect their grades.³⁵

THE RESPONSE TO IDENTIFIED PSYCHOSOCIAL NEEDS

1. Youth-Friendly Services

HIV Disclosure, Confidentiality, and Stigma

- (a) Confidentiality and privacy policies should be implemented. Given that homophobia, discrimination, and violence often affect HIV-positive LGBT adolescents and young adults, better outcomes are reported in health care settings where there are confidentiality and privacy policies that are discussed during enrollment and at subsequent clinic visits.^{18,36,37} Standard forms for and policies on confidentiality as well as policies on privacy for youth are available and can be modified as state or local jurisdictions legally permit.³⁸
- (b) HIV stigma should be addressed within a developmentally appropriate unit offering comprehensive medical services like a medical home,¹⁶ with patients engaged in trusting relationships with health care providers and being kept well informed of the status of their illness.^{16,39}

Denial and Coping With the Diagnosis of HIV Infection

- (c) Services should address how youth can cope with their HIV

diagnosis. Infrastructure in the medical home that promotes coping through family, peer groups, and spiritual groups as well as professional involvement can improve adherence to clinic appointments and ARV therapy.¹⁶

Case Management and Multidisciplinary Care in the Medical Home

- (d) The sole provision of medical treatment is not sufficient to engage and retain HIV-infected youth in care. Service models that include consideration of gender, race and ethnicity, developmental stage, mental health, family composition, peer reference groups and relationships, economic resources, sexuality, and sexual behaviors are more likely to improve outcomes.⁴⁰
- (e) Effective medical treatment should be inclusive of flexible scheduling and a multidisciplinary team approach that includes aggressive case management and care coordination.^{41,42}
- (f) Patients should be assigned to a physician-led medical home team that can regularly provide all of the medical services and continuity of care.⁴¹
- (g) Medical care services should facilitate prompt access to mental health services.
- (h) Regular multidisciplinary team meetings should be scheduled to include all providers involved in the patient's care.

2. Structural Program Elements

- (a) Addressing barriers to health care use may assist youth in improving disease self-management. Perceived needs in 1 study of 107 HIV-infected youth included access to mental health services (45%), alcohol and drug treatment (14%), transportation to health care

settings (40%), and housing (47%). Youth who expressed these needs were unable or unwilling to “focus on accessing” HIV comprehensive health care.^{41,43}

- (b) Youth buddies are peer advocates who conduct peer-to-peer counseling. When youth buddies are used as part of the comprehensive medical services team, they can be effective in engaging and retaining youth in care.⁴¹

3. Social Media

Health Insurance Portability and Accountability Act-compliant secure messaging through the Internet, mobile phones, and social media can be used for improving appointment and medication adherence. Almost all adolescents and young adults have used the Internet

and mobile phones in their daily lives.⁴⁴ Ninety-five percent of youth report using the Internet and are avid users of social media, with 90% of 13- to 17-year-olds reporting its use, 80% reporting a current profile on a social network site, and 22% having a Twitter account.^{45–50}

4. Advocacy

Pediatricians should advocate for resources that are necessary to provide optimal care for HIV-infected adolescents and young adults to include social support, rehabilitation, education, and access to basic necessities, including stable housing, without which the best medical care may prove ineffective. Pediatricians can advocate at the community and legislative/public policy levels (<http://www.aap.org/en-us/advocacy-and-policy/Pages/Advocacy-and-Policy.aspx>).

abstract

FREE

The purpose of this statement is to update recommendations for routine use of seasonal influenza vaccine and antiviral medications for the prevention and treatment of influenza in children. The American Academy of Pediatrics recommends annual seasonal influenza immunization for *all* people 6 months and older, including all children and adolescents. Highlights for the upcoming 2014–2015 season include the following:

1. The influenza vaccine composition for the 2014–2015 season is *unchanged* from the 2013–2014 season.
2. Both trivalent and quadrivalent influenza vaccines are available in the United States for the 2014–2015 season.
3. Annual universal influenza immunization is indicated with either a trivalent or quadrivalent vaccine (no preference).
4. Live attenuated influenza vaccine (LAIV) should be considered for *healthy* children 2 through 8 years of age who have no contraindications or precautions to the intranasal vaccine. If LAIV is not readily available, inactivated influenza vaccine (IIV) should be used; vaccination should not be delayed to obtain LAIV.
5. The dosing algorithm for administration of influenza vaccine to children 6 months through 8 years of age reflects that virus strains in the vaccine have not changed from last season.

As always, pediatricians, nurses, and all other health care personnel should be immunized themselves and should promote influenza vaccine use and infection control measures. In addition, pediatricians should promptly identify clinical influenza infections to enable rapid antiviral treatment, when indicated, to reduce morbidity and mortality. *Pediatrics* 2014;134:e1503–e1519

INTRODUCTION

The American Academy of Pediatrics (AAP) recommends annual seasonal influenza immunization for *all* people 6 months and older, including all children and adolescents, during the 2014–2015 influenza season. In addition, special effort should be made to vaccinate people in the following groups:

- All children, including infants born preterm, who are 6 months and older with conditions that increase the risk of complications from influenza (eg, children with chronic medical conditions, such as asthma, diabetes mellitus, hemodynamically significant cardiac disease, immunosuppression, or neurologic and neurodevelopmental disorders);
- Children of American Indian or Alaska Native heritage
- All household contacts and out-of-home care providers of
 - Children with high-risk conditions
 - Children younger than 5 years, especially infants younger than 6 months
- All health care personnel (HCP)
- All child care providers and staff
- All women who are pregnant, are considering pregnancy, are in the postpartum period, or are breastfeeding during the influenza season

KEY POINTS RELEVANT FOR THE 2014–2015 INFLUENZA SEASON

1. **Annual seasonal influenza vaccine is recommended for all people 6 months and older, including all children and adolescents, during the 2014–2015 influenza season.** It is important that household contacts and out-of-home care providers of children younger than 5 years, especially infants younger than 6 months, and children of any age at high risk of complications from influenza (eg, children with chronic medical conditions, such as asthma, diabetes mellitus, hemodynamically significant cardiac disease, immunosuppression, or neurologic and neurodevelopmental disorders) receive annual influenza vaccine. In the United States,

more than two-thirds of children younger than 6 years and almost all children 6 years and older spend significant time in child care or school settings outside the home. Exposure to groups of children increases the risk of contracting infectious diseases. Children younger than 2 years are at elevated risk of hospitalization and complications attributable to influenza. School-aged children bear a large influenza disease burden and have a significantly higher chance of seeking influenza-related medical care compared with healthy adults. Reducing influenza virus transmission (eg, appropriate hand hygiene, respiratory hygiene/cough etiquette) among children who attend out-of-home child care or school has been shown to decrease the burden of childhood influenza and transmission of influenza virus to household contacts and community members of all ages.

2. The percentage of outpatient visits for influenza-like illness, rates of hospitalization, and deaths attributed to pneumonia and influenza were lower during the 2013–2014 influenza season when compared with the previous season. As of August 23, 2014, 107 laboratory-confirmed influenza-associated pediatric deaths were reported to the Centers for Disease Control and Prevention (CDC) during the 2013–2014 influenza season. The 2009 influenza A (H1N1) pandemic (pH1N1) viruses predominated, but influenza A (H3N2) and influenza B viruses also were reported in the United States. Of the 107 deaths, 87 were associated with influenza A viruses, and 16 deaths were associated with influenza B viruses. Two deaths were associated with an undetermined type of influenza

virus, and 2 deaths were associated with dual infection with both influenza A and B viruses. Although children with certain conditions are at higher risk of complications, 47% of the deaths occurred in children with no high-risk underlying medical condition. Among children hospitalized with influenza and for whom medical chart data were available, approximately 43% had no recorded underlying condition, whereas 26% had underlying asthma or reactive airway disease (Fig 1). A recent preliminary observation of the 2013–2014 influenza season noted a high number of healthy people (ranging from infants to older adults) who needed care in the ICU, 91% of whom were not previously vaccinated.

3. Both trivalent and quadrivalent influenza vaccines are available in the United States for the 2014–2015 season. Neither vaccine formulation is preferred over the other. Both vaccines contain an A/California/7/2009 (H1N1)–like virus, an A/Texas/50/2012 (H3N2) virus, and a B/Massachusetts/2/2012–like virus (B/Yamagata lineage). The quadrivalent influenza vaccines include an additional B virus (B/Brisbane/60/2008–like virus [B/Victoria lineage]). These strains are unchanged from those in the 2013–2014 seasonal influenza vaccines.
4. Optimal protection is achieved through annual immunization. Antibody titers wane to 50% of their original levels 6 to 12 months after vaccination. Although the vaccine strains for the 2014–2015 season are unchanged from last season, a repeat dose this season is critical for maintaining protection in all populations.
5. Using the Grading of Recommendations Assessment, Development,

**FIGURE 1**

Selected underlying medical conditions in patients hospitalized with laboratory-confirmed influenza, FluSurv-NET 2013–2014. Source: Centers for Disease Control and Prevention. FluView 2013–2014 Preliminary Data as of August 23, 2014. Available at: <http://gis.cdc.gov/grasp/fluview/FluHospChars.html>. Asthma includes a medical diagnosis of asthma or reactive airway disease. Cardiovascular diseases include conditions such as coronary heart disease, cardiac valve disorders, congestive heart failure, pulmonary hypertension, and aortic stenosis; does not include hypertension disease only. Chronic lung diseases include conditions such as chronic obstructive pulmonary disease, bronchiolitis obliterans, chronic aspiration pneumonia, and interstitial lung disease. Immune suppression includes conditions such as immunoglobulin deficiency, leukemia, lymphoma, HIV/AIDS, and the use of immunosuppressive medications. Metabolic disorders include conditions such as diabetes mellitus, thyroid dysfunction, adrenal insufficiency, and liver disease. Neurologic disorders include conditions such as seizure disorders, cerebral palsy, and cognitive dysfunction. Neuromuscular disorders include conditions such as multiple sclerosis and muscular dystrophy. Obesity was assigned if indicated in patient's medical chart or if BMI >30 kg/m². Pregnancy percentage calculated by using number of female cases aged between 15 and 44 years of age as the denominator. Renal diseases include conditions such as acute or chronic renal failure, nephrotic syndrome, glomerulonephritis, and impaired creatinine clearance. No known condition indicates that the case did not have any known underlying medical condition indicated in medical chart at the time of hospitalization.

and Evaluation (GRADE) framework, the CDC Advisory Committee on Immunization Practices (ACIP) systematically reviewed the evidence pertaining to the efficacy of live attenuated influenza vaccine (LAIV) and inactivated influenza vaccine (IIV) for healthy children. It concluded that there is greater relative efficacy of LAIV as compared with IIV against laboratory-confirmed influenza among younger children (based on 2 studies including children up to 6 years of

age). The risk of adverse events after immunization, including fever, wheezing, and serious adverse events, appears to be similar for LAIV and IIV. Therefore, LAIV should be considered for *healthy* children 2 through 8 years of age who have no contraindications or precautions to the intranasal vaccine. If LAIV is not readily available, IIV should be used; vaccination should not be delayed to obtain LAIV. The age of 8 years is selected as the upper limit for this recommenda-

tion on the basis of demonstration of superior efficacy of LAIV (ages 2 through 6 years) and for programmatic consistency (8 years is the upper age limit for receipt of 2 doses of influenza vaccine in a previously unvaccinated child).

6. The number of seasonal influenza vaccine doses to be administered in the 2014–2015 influenza season depends on the child's age at the time of the first administered dose and his or her vaccine history (Fig 2):

- Influenza vaccines are not licensed for administration to infants younger than 6 months.
- Children 9 years and older need only 1 dose.
- Children 6 months through 8 years of age receiving the seasonal influenza vaccine *for the first time* should receive a second dose this season at least 4 weeks after the first dose.
- Children 6 months through 8 years of age need only 1 dose of vaccine in 2014–2015 if they have received it according to any of the following scenarios:
 - ✓ At least 1 dose of 2013–2014 seasonal influenza vaccine.
 - ✓ 2 or more doses of seasonal vaccine since July 1, 2010.
 - ✓ 2 or more doses of seasonal influenza vaccine from any previous season and at least 1 clearly documented dose of a pH1N1-containing vaccine (ie, any seasonal vaccine since July 1, 2010 or a monovalent pH1N1 vaccine during the 2009–2010 season).

Children in this age group for whom one of these conditions is not met need 2 doses in 2014–2015 to be adequately primed. Vaccination should not be delayed to obtain a specific product for either dose. Any available, age-appropriate trivalent or quadrivalent vaccine can be used; IIV and LAIV are considered interchangeable. A child who receives only 1 of the 2 doses as a quadrivalent formulation is likely to be less primed against the additional B virus.

7. Pediatric offices may choose to serve as an alternative venue for

providing influenza immunization for parents and other care providers of children if the practice is acceptable to both pediatricians and the adults who are to be vaccinated.¹ There are important medical liability issues and medical record documentation requirements that must be addressed before a pediatrician begins immunizing adults (see details at www.aapredbook.org/implementation). Pediatricians are reminded to document the recommendation for adult immunization in the vulnerable child's medical record. In addition, adults should still be encouraged to have a medical home and communicate their immunization status to their primary care provider. Offering immunizations in the pediatric practice setting would not be intended to undermine the adult medical home model but could serve as an additional venue for parents and other care providers for children to receive vaccinations. Immunization of close contacts of children at high risk of influenza-related complications is intended to reduce their risk of contagion (ie, "cocooning"). The practice of cocooning may help protect infants younger than 6 months, because they are too young to be immunized with influenza vaccine. Infants younger than 6 months also can be protected through vaccination of their mothers during pregnancy, with resulting transplacental transfer of antibodies. The risk of influenza-associated hospitalization in healthy children younger than 24 months has been shown to be greater than the risk of hospitalization in previously recognized high-risk groups, such as older adults, during influenza season. Children 24 through 59 months of age have

shown higher rates of outpatient visits and antimicrobial use associated with influenza-like illnesses than older children.

8. As soon as the seasonal influenza vaccine is available locally, pediatricians or vaccine administrators should immunize HCP, notify parents and caregivers of vaccine availability and the importance of annual vaccination, and immunize children 6 months and older per recommendations, especially those at high risk of complications from influenza. Health care provider endorsement plays a major role in vaccine uptake. A strong correlation exists between health care provider endorsement of influenza vaccine and patient acceptance. Prompt initiation of influenza immunization and continuance of immunization throughout the influenza season, whether or not influenza is circulating (or has circulated) in the community, are critical components of an effective immunization strategy. Administering the vaccine early during the influenza season is not believed to pose a significant risk that immunity might wane before the end of the season. The seasonal vaccine is not 100% effective, but it still is the best strategy available for preventing illness from influenza. It is moderately effective in reducing the risk for outpatient medical visits caused by circulating influenza viruses by approximately one-half to three-quarters in most people. Even during seasons when the vaccine is only moderately effective, influenza vaccine has been shown to reduce illness, antibiotic use, doctor visits, time lost from work, hospitalizations, and deaths.
9. Providers should continue to offer vaccine until the vaccine expiration

Number of 2014–2015 Seasonal Influenza Vaccine Doses for Children 6 Months Through 8 Years of Age

FIGURE 2

Number of 2014–2015 seasonal influenza vaccine doses for children 6 months through 8 years of age. For simplicity, this algorithm takes into consideration only doses of seasonal influenza vaccine received since July 1, 2010. As an alternative approach in settings where vaccination history from before July 1, 2010 is available, if a child aged 6 months through 8 years is known to have received 2 or more doses of seasonal influenza vaccine from any previous season *and* at least 1 clearly documented dose of a pH1N1-containing vaccine (ie, any seasonal vaccine since July 1, 2010 or a monovalent pH1N1 vaccine during the 2009–2010 season), then the child needs only 1 dose for 2014–2015.

date (June 30, marking the end of the influenza season), because influenza is unpredictable. Protective immune responses persist throughout the influenza season, which can have >1 disease peak and may extend into March or later. Although the peak of influenza activity in the United States tends to occur in January through March, influenza activity can occur in early fall (ie, October and November) or late spring (eg, influenza circulated through the end of May during the 2013–2014 season). This approach also provides ample opportunity to administer a second dose of vaccine when indicated, as detailed in Key Point 6 above. In addition, international travel may result in potential exposure to influenza throughout the year.

10. HCP, influenza campaign organizers, and public health agencies

should collaborate to develop improved strategies for planning, communication, and administration of vaccines.

- Plan to make seasonal influenza vaccine easily accessible for all children. Examples include alerts to families that vaccine is available (eg, e-mails, texts, and patient portals); creating walk-in influenza clinics; extending hours beyond routine times during peak vaccination periods; administering influenza vaccine during both well and sick visits; considering how to immunize parents, adult caregivers, and siblings at the same time in the same office setting as children¹; and working with other institutions (eg, schools, child care programs, and religious organizations) or alter-

native care sites, such as emergency departments, to expand venues for administering vaccine. If a child or adult receives influenza vaccine outside his or her medical home, such as at a pharmacy, retail-based clinic, or another practice, appropriate documentation of immunization should be provided to the patient for his or her medical home and entered into the state immunization registry where possible.

- Concerted efforts among the aforementioned groups, plus vaccine manufacturers, distributors, and payers, also are necessary to prioritize distribution appropriately to the primary care office setting and patient-centered medical home before other venues, especially when vaccine supplies are delayed or limited.
 - Vaccine safety, effectiveness, and indications must be communicated properly to the public. Pediatricians and office staff should explain the importance of annual influenza vaccination for children and emphasize when a second dose of vaccine is indicated. HCP should act as role models by receiving influenza immunization annually and recommending annual immunizations to both colleagues and patients. Influenza immunization programs for HCP benefit the health of employees, their patients, and members of the community.²
11. Antiviral medications also are important in the control of influenza but are not a substitute for influenza immunization. The neuraminidase inhibitors (NAIs) oral oseltamivir (Tamiflu; Roche Laboratories, Nutley, NJ) and inhaled

zanamivir (Relenza; GlaxoSmithKline, Research Triangle Park, NC) are the only antiviral medications recommended for chemoprophylaxis or treatment of influenza during the 2014–2015 season. Intravenous preparations of oseltamivir, zanamivir, and peramivir are not approved by the US Food and Drug Administration (FDA). However, in consultation with infectious diseases specialists, investigational intravenous zanamivir should be considered for critically ill children, especially those who are immunocompromised or cannot tolerate or absorb oral or enterically administered oseltamivir. Recent viral surveillance and resistance data indicate that the majority of currently circulating influenza viruses likely to cause 2014–2015 seasonal influenza in North America continue to be sensitive to oseltamivir and zanamivir. In contrast, amantadine and rimantadine should not be used, because circulating influenza A viruses currently have levels of resistance to these drugs, and they are not effective against influenza B viruses. Because resistance characteristics can change rapidly, pediatricians should verify susceptibility data at the start of the influenza season and monitor them throughout the season. Up-to-date information can be found on the AAP Web site (www.aap.org or www.aapredbook.org/flu), through state-specific AAP chapter Web sites, or on the CDC Web site (www.cdc.gov/flu/index.htm).

SEASONAL INFLUENZA VACCINES

Before the 2013–2014 influenza season, only trivalent influenza vaccines that included a single influenza B strain were available. However, since 1985, 2 antigenically distinct lineages (ie, Victoria or Yamagata) of influenza

B viruses have circulated globally. Vaccination against 1 B viral lineage confers little cross-protection against the other B viral lineage. Thus, trivalent vaccines offer limited immunity against circulating influenza B strains of the lineage not present in the vaccine. Furthermore, in recent years it has proven difficult to predict consistently which B lineage will predominate during a given influenza season. Therefore, a quadrivalent influenza vaccine with influenza B strains of *both* lineages should offer greater protection. Post-marketing safety and vaccine effectiveness data are not yet available, precluding a full risk–benefit analysis of newer versus previously available products.

For the 2014–2015 season, IIVs will be available for intramuscular (IM) injection in both trivalent (IIV3) and quadrivalent (IIV4) formulations. The intranasally administered LAIV will be available only in a quadrivalent formulation (LAIV4). All quadrivalent vaccines will contain the identical influenza strains anticipated to circulate during the 2014–2015 influenza season.

IIVs contain no live virus. IIV3 formulations are available for IM and intradermal (ID) use. The IM formulation of IIV3 is licensed and recommended for children 6 months and older and adults, including people with and without chronic medical conditions. The most common adverse events after IIV administration are local injection site pain and tenderness. Fever may occur within 24 hours after immunization in approximately 10% to 35% of children younger than 2 years but rarely in older children and adults. Mild systemic symptoms, such as nausea, lethargy, headache, muscle aches, and chills, may occur after administration of IIV3.

An ID formulation of IIV3 is licensed for use in people 18 through 64 years of age. ID vaccine administration involves

a microinjection with a shorter needle than needles used for IM administration. The most common adverse events are redness, induration, swelling, pain, and itching, which occur at the site of administration; although all adverse events occur at a slightly higher rate with the IM formulation of IIV3, the rate of pain was similar between ID and IM. Headache, myalgia, and malaise may occur and tend to occur at the same rate as that with the IM formulation of IIV3. There is no preference for IM or ID immunization with IIV3 in people 18 years or older. Therefore, pediatricians may choose to use either the IM or ID product for their young adult patients and for any adults they are vaccinating (ie, as part of a cocooning strategy).

IIV4 is available in IM but not ID formulations. One formulation of IIV4 is licensed for use in children as young as 6 months of age. In children, the most common injection site adverse reactions were pain, redness, and swelling. The most common systemic adverse events were drowsiness, irritability, loss of appetite, fatigue, muscle aches, headache, arthralgia, and gastrointestinal tract symptoms. These events were reported with comparable frequency among participants receiving the licensed comparator trivalent vaccines. IIV4 is an acceptable vaccine for people 6 months or older when otherwise appropriate and may offer broader protection than IIV3. The relative quantity of doses of IIV4 that will be available is not certain and likely to be limited.

During the 2 influenza seasons spanning 2010–2012, there were increased reports of febrile seizures in the United States in young children who received IIV and the 13-valent pneumococcal conjugate vaccine (PCV13) concomitantly, but this has not been observed in more recent seasons. Simultaneous administration of IIV and

PCV13 for the 2014–2015 influenza season continues to be recommended when both vaccines are indicated.

LAIV4 is a quadrivalent live attenuated influenza vaccine that is administered intranasally. It is licensed by the FDA for previously healthy people 2 through 49 years of age. The most commonly reported reactions in children were runny nose or nasal congestion, headache, decreased activity or lethargy, and sore throat. LAIV4 should not be administered to people with notable nasal congestion that would impede vaccine delivery. The safety of LAIV in people with a history of asthma, diabetes mellitus, or other high-risk medical conditions associated with an elevated risk of complications from influenza (see Contraindications and Precautions) has not been established. In a postlicensure surveillance of LAIV over 7 seasons, the Vaccine Adverse Event Reporting System (VAERS), jointly sponsored by the FDA and CDC, did not identify any new or unexpected safety concerns, although there were reports of use of LAIV in people with a contraindication or precaution. The use of LAIV in young children with chronic medical conditions, including asthma, has been implemented outside the United States, but the vaccine is not licensed for these indications in the United States.

Two trivalent influenza vaccines manufactured using technologies that do not use eggs will also be available for people 18 years or older during the 2014–2015 season: cell culture–based inactivated influenza vaccine (ccIIV3) and recombinant influenza vaccine (RIV3). These manufacturing methods would probably permit a more rapid scale-up of vaccine production when needed, such as during a pandemic.

ccIIV3 is a trivalent cell culture–based inactivated influenza vaccine indicated for people 18 years or older, administered as an IM injection. ccIIV3 has comparable immunogenicity to US-

licensed IIV3 comparator vaccines. Although ccIIV3 is manufactured from virus propagated in Madin Darby canine kidney cells rather than embryonated eggs, before production, seed virus is created from the World Health Organization reference virus strains, which have been passaged in eggs. However, egg protein is not detectable in the final vaccine, and egg allergy is not mentioned as a contraindication in the package insert. Other contraindications to vaccine delivery are similar to those for other IIVs. The most common solicited adverse reactions included injection site pain, erythema at the injection site, headache, fatigue, myalgia, and malaise.

RIV3 is a recombinant baculovirus–expressed hemagglutinin vaccine produced in cell culture. It is indicated for people 18 through 49 years of age and is administered via IM injection. The most frequently reported adverse events were pain, headache, myalgia, and fatigue. There are no egg proteins in this version of influenza vaccine.

Tables 1 and 2 summarize information on the types of 2014–2015 seasonal influenza vaccines licensed for immunization of children and adults. It is likely that more than 1 type or brand of vaccine may be appropriate for vaccine recipients. However, vaccination should not be delayed to obtain a specific product.

A large body of scientific evidence demonstrates that thimerosal-containing vaccines are not associated with elevated risk of autism spectrum disorders in children. Therefore, the AAP extends its strongest support to the recent World Health Organization recommendations to retain the use of thimerosal in the global vaccine supply. Some people may still raise concerns about the minute amounts of thimerosal in IIV vaccines, and in some states there is a legislated restriction on the use of thimerosal-containing vaccines.

The benefits of protecting children against the known risks of influenza are clear. Therefore, children should receive any available formulation of IIV rather than delaying immunization while waiting for reduced thimerosal-content or thimerosal-free vaccines. Although some formulations of IIV contain only a trace amount of thimerosal, certain types can be obtained thimerosal free. LAIV4 does not contain thimerosal. Vaccine manufacturers are delivering increasing amounts of thimerosal-free influenza vaccine each year.

INFLUENZA VACCINES AND EGG ALLERGY

Although most IIV and LAIV vaccines are produced in eggs and contain measurable amounts of egg protein, recent data have shown that IIV administered in a single, age-appropriate dose is well tolerated by most recipients with a history of egg allergy. More conservative approaches in children with a history of egg allergy, such as skin testing or a 2-step graded challenge, no longer are recommended. No data have been published on the safety of administering LAIV to egg-allergic recipients.

As a precaution, pediatricians should continue to determine whether the presumed egg allergy is based on a mild (ie, hives alone) or severe reaction (ie, anaphylaxis involving cardiovascular changes, respiratory or gastrointestinal tract symptoms, or reactions that necessitate the use of epinephrine). Pediatricians should consult with an allergist for children with a history of severe reaction. Most vaccine administration to patients with egg allergy can occur without the need for referral. Data indicate that only approximately 1% of children have immunoglobulin E–mediated sensitivity to egg, and of those, a rare minority have a severe allergy. The Joint Task Force on Practice Parameters,

TABLE 1 Recommended Seasonal Influenza Vaccines for Different Age Groups: United States, 2014–2015 Influenza Season

Vaccine	Trade Name	Manufacturer	Presentation	Thimerosal Mercury Content (µg of Hg per 0.5-mL dose)	Age Group
Inactivated					
IIV3	Fluzone	Sanofi Pasteur	0.25-mL prefilled syringe	0	6–35 mo
			0.5-mL prefilled syringe	0	≥36 mo
			0.5-mL vial	0	≥36 mo

Sources: American Academy of Pediatrics, Committee on Infectious Diseases. Recommendations for prevention and control of influenza in children, 2013–2014. *Pediatrics*. 2013;132(4):e1089–e1104; and Centers for Disease Control and Prevention. Prevention and control of seasonal influenza with vaccines: recommendations of the Advisory Committee on Immunization Practices (ACIP)—United States, 2014–2015 influenza season. *MMWR Recomm Rep*. 2014;63(32):691–697.

^a Age indication per package insert is ≥5 y; however, the Advisory Committee on Immunization Practices recommends Afluria not be used in children 6 mo through 8 y of age because of febrile reactions reported in this age group. If no other age-appropriate, licensed inactivated seasonal influenza vaccine is available for a child 5 through 8 y of age who has a medical condition that increases the child's risk of influenza complications, Afluria can be used; however, pediatricians should discuss with the parents or caregivers the benefits and risks of influenza vaccination with Afluria before administering this vaccine.

representing the American Academy of Allergy, Asthma & Immunology (AAAAI) and the American College of Allergy, Asthma & Immunology (ACAAI), recently published an updated recommendation that special precautions regarding medical setting and waiting periods after administration of IIV to egg-allergic recipients beyond those recommended for any vaccine are not warranted. This concept has not been universally accepted by all allergists, so the AAP recommendation has not changed.

Standard immunization practice should include the ability to respond to acute hypersensitivity reactions. Therefore, influenza vaccine should be given to children with egg allergy with the following preconditions (Fig 3):

- Appropriate resuscitative equipment must be readily available.³
- The vaccine recipient should be observed in the office for 30 minutes after immunization, the usual observation time for receiving immunotherapy.

Providers may consider use of cclIV3 or RIV3 vaccines produced via non-egg-based technologies for patients 18 years or older with egg allergy in settings in which these vaccines are available and otherwise age appropriate. cclIV3, which does contain trace amounts of ovalbumin, should be administered according to the guidance for other IIVs (Fig 3). RIV3, which contains no ovalbumin, may be administered to people with egg allergy of any

severity who are 18 through 49 years of age and do not have other contraindications. However, vaccination of patients with mild egg allergy should not be delayed if RIV3 or cclIV3 is not available. Instead, any licensed, age-appropriate IIV should be used.

VACCINE STORAGE AND ADMINISTRATION

The AAP Storage and Handling Tip Sheet provides resources for practices to develop comprehensive vaccine management protocols to keep the temperature for vaccine storage constant during a power failure or other disaster (www2.aap.org/immunization/pediatricians/pdf/DisasterPlanning.pdf).

TABLE 2 LAIV4 Compared With IIV3 and IIV4

Vaccine Characteristic	LAIV4	IIV3	IIV4
Route of administration	Intranasal spray	Intramuscular or intradermal injection ^a	Intramuscular injection ^a
Type of vaccine	Live virus	Killed virus	Killed virus
Product	Attenuated, cold adapted	Inactivated subvirion or surface antigen	Inactivated subvirion or surface antigen
No. of included virus strains	4 (2 influenza A, 2 influenza B)	3 (2 influenza A, 1 influenza B)	4 (2 influenza A, 2 influenza B)
Vaccine virus strains updated	Annually	Annually	Annually
Frequency of administration ^b	Annually	Annually	Annually
Approved age groups	All healthy people aged 2–49 y	All people aged ≥6 mo (ID 18–64 y)	All people aged ≥6 mo
Interval between 2 doses in children	4 wk	4 wk	4 wk
Can be given to people with medical risk factors for influenza-related complications?	Not preferred	Yes	Yes
Can be given to children with asthma or children aged 2–4 y with wheezing in the previous year?	No ^c	Yes	Yes
Can be simultaneously administered with other vaccines?	Yes ^d	Yes ^d	Yes ^d
If <i>not</i> simultaneously administered, can be administered within 4 wk of another live vaccine?	No, recommended to space 4 wk apart	Yes	Yes
Can be administered within 4 wk of an inactivated vaccine?	Yes	Yes	Yes

Sources: American Academy of Pediatrics, Committee on Infectious Diseases. Recommendations for prevention and control of influenza in children, 2013–2014. *Pediatrics*. 2013;132(4):e1089–e1104; and Centers for Disease Control and Prevention. Prevention and control of seasonal influenza with vaccines: recommendations of the Advisory Committee on Immunization Practices (ACIP)—United States, 2014–2015 influenza season. *MMWR Recomm Rep*. 2014;63(32):691–697.

^a The preferred site of IIV intramuscular injection for infants and young children is the anterolateral aspect of the thigh.

^b See Fig 2 for decision algorithm to determine number of doses of seasonal influenza vaccine recommended for children during the 2014–2015 influenza season.

^c LAIV4 is not recommended for children with a history of asthma. In the 2- through 4-y age group, there are children who have a history of wheezing with respiratory illnesses in whom reactive airway disease is diagnosed and in whom asthma may later be diagnosed. Therefore, because of the potential for increased wheezing after immunization, children 2 through 4 y of age with recurrent wheezing or a wheezing episode in the previous 12 mo should not receive LAIV4. When offering LAIV4 to children in this age group, a pediatrician should screen those who might be at higher risk of asthma by asking the parents or guardians of 2-, 3-, and 4-y-olds (24- through 59-mo-olds) the question, “In the previous 12 months, has a health care professional ever told you that your child had wheezing?” If the parents answer “yes” to this question, LAIV4 is not recommended for these children.

^d LAIV4 coadministration has been evaluated systematically only among children 12–15 mo of age with measles–mumps–rubella and varicella vaccines. IIV coadministration has been evaluated systematically only among adults with pneumococcal polysaccharide and zoster vaccines.

Any of the influenza vaccines can be administered at the same visit with all other recommended routine vaccines.

Intramuscular Vaccine

The IM formulation of IIV is shipped and stored at 2°C to 8°C (35°F–46°F). It is administered intramuscularly into the anterolateral thigh of infants and young children and into the deltoid muscle of older children and adults. The volume of vaccine is age dependent; infants and toddlers 6 months through 35 months of age should receive a dose of 0.25 mL, and all people 3 years (36 months) and older should receive 0.5 mL/dose.

Intradermal Vaccine

The ID formulation of IIV also is shipped and stored at 2°C to 8°C (35°F–46°F). It is administered intradermally only to people 18 through 64 years of age,

preferably over the deltoid muscle and only using the device included in the vaccine package. Vaccine is supplied in a single-dose, prefilled microinjection system (0.1 mL) for adults. The package insert should be reviewed for full administration details of this product.

Live Attenuated (Intranasal) Vaccine

The cold-adapted, temperature-sensitive LAIV4 formulation currently licensed in the United States must be shipped and stored at 2°C to 8°C (35°F–46°F) and administered intranasally in a prefilled, single-use sprayer containing 0.2 mL of vaccine. A removable dose divider clip is attached to the sprayer to administer 0.1 mL separately into each nostril. After administration of any live virus vaccine, at least 4 weeks should pass before another live virus vaccine is administered.

CURRENT RECOMMENDATIONS

Seasonal influenza immunization is recommended for all children 6 months and older. LAIV should be considered for *healthy* children 2 through 8 years of age who have no contraindications or precautions to the intranasal vaccine. This is based on a GRADE analysis done by the CDC, which concluded that there is greater relative efficacy of LAIV as compared with IIV against laboratory-confirmed influenza among younger children. If LAIV is not readily available, IIV should be used; vaccination should not be delayed to obtain LAIV. Particular focus should be on the administration of IIV for all children and adolescents with underlying medical conditions associated with an elevated risk of complications from influenza, including the following:

- Asthma or other chronic pulmonary diseases, including cystic fibrosis

Approach to Children With Presumed Egg Allergy

FIGURE 3

Precautions for administering IIV to presumed egg-allergic children.

- Hemodynamically significant cardiac disease
- Immunosuppressive disorders or therapy
- HIV infection
- Sickle cell anemia and other hemoglobinopathies
- Diseases that necessitate long-term aspirin therapy, including juvenile idiopathic arthritis or Kawasaki disease
- Chronic renal dysfunction
- Chronic metabolic disease, including diabetes mellitus
- Any condition that can compromise respiratory function or handling of secretions or can increase the risk of aspiration, such as neu-

rodevelopmental disorders, spinal cord injuries, seizure disorders, or neuromuscular abnormalities

Although universal immunization for all people 6 months and older is recommended for the 2014–2015 influenza season, particular immunization efforts with either IIV or LAIV should be made for the following groups to prevent transmission of influenza to those at risk, unless contraindicated:

- Household contacts and out-of-home care providers of children younger than 5 years and at-risk children of all ages (healthy contacts 2 through 49 years of age can receive either IIV or LAIV).
- Any woman who is pregnant or considering pregnancy (IIV only),

is in the postpartum period, or is breastfeeding during the influenza season. Studies have shown that infants born to immunized women have better influenza-related health outcomes. However, according to Internet panel surveys conducted by the CDC, only 51% of pregnant women reported receiving an influenza vaccine during the 2012–2013 season, even though both pregnant women and their infants are at higher risk of complications. In addition, data from some studies suggest that influenza vaccination in pregnancy may decrease the risk of preterm birth and of giving birth to infants who are small for gestational age. Pregnant women can receive the

influenza vaccine safely during any trimester.

- Children and adolescents of American Indian or Alaska Native heritage.
- HCP or health care volunteers. Despite the AAP recommendation for mandatory influenza immunization for all HCP,² many remain unvaccinated. As of November 2013, the CDC estimated that only 62.9% of HCP received the seasonal influenza vaccine. The AAP recommends mandatory vaccination of HCP, because HCP frequently come into contact with patients at high risk of influenza illness in their clinical settings.
- Close contacts of immunosuppressed people.

CONTRAINDICATIONS AND PRECAUTIONS

Minor illnesses, with or without fever, are not contraindications to the use of influenza vaccines, particularly among children with mild upper respiratory infection symptoms or allergic rhinitis.

Children Who Should Not Be Vaccinated With IIV

- Infants younger than 6 months.
- Children who have a moderate to severe febrile illness, on the basis of clinical judgment of the clinician.

Children Who Should Not Be Vaccinated With LAIV

- Children younger than 2 years.
- Children who have a moderate to severe febrile illness.
- Children with an amount of nasal congestion that would notably impede vaccine delivery.
- Children 2 through 4 years of age with a history of recurrent wheezing or a medically attended wheezing

episode in the previous 12 months because of the potential for increased wheezing after immunization. In this age range, many children have a history of wheezing with respiratory tract illnesses and are eventually diagnosed with asthma. Therefore, when offering LAIV to children 24 through 59 months of age, the pediatrician should screen them by asking the parent or guardian, “In the previous 12 months, has a health care professional ever told you that your child had wheezing?” If a parent answers “yes” to this question, LAIV is *not* recommended for the child. IIV would be recommended for the child to whom LAIV is not given.

- Children with the diagnosis of asthma.
- Children with a history of egg allergy.
- Children who have received other live virus vaccines within the last 4 weeks; however, other live virus vaccines can be given on the same day as LAIV.
- Children who have known or suspected immunodeficiency disease or who are receiving immunosuppressive or immunomodulatory therapies.
- Children who are receiving aspirin or other salicylates.
- Any woman who is pregnant or considering pregnancy.
- Children with any condition that can compromise respiratory function or handling of secretions or can increase the risk for aspiration, such as neurodevelopmental disorders, spinal cord injuries, seizure disorders, or neuromuscular abnormalities.
- Children taking an influenza antiviral medication should not receive LAIV until 48 hours after stopping the influenza antiviral therapy. If a child recently received LAIV but

has an influenza illness for which antiviral agents are appropriate, the antiviral agents should be given. Reimmunization may be indicated because of the potential effects of antiviral medications on LAIV replication and immunogenicity.

Children for Whom IIV Is Preferred

- Children with chronic underlying medical conditions, including metabolic disease, diabetes mellitus, other chronic disorders of the pulmonary or cardiovascular systems, renal dysfunction, or hemoglobinopathies. The safety of LAIV in these populations has not been established. These conditions are not contraindications but are listed under the “Warnings and Precautions” section of the LAIV package insert. A precaution is a condition in a recipient that might increase the risk or seriousness of an adverse reaction or complicate making another diagnosis because of a possible vaccine-related reaction. A precaution also may exist for conditions that might compromise the ability of the vaccine to produce immunity. Vaccination may be recommended in the presence of a precaution if the benefit of protection from the vaccine outweighs any risk.

IIV is the vaccine of choice for anyone in close contact with a subset of severely immunocompromised people (ie, those in a protected environment). IIV is preferred over LAIV for contacts of severely immunocompromised people because of the theoretical risk of infection attributable to LAIV strain in an immunocompromised contact of an LAIV-immunized person. Available data indicate a very low risk of transmission of the virus in both children and adults vaccinated with LAIV. HCP immunized with LAIV may continue to work in most units of a hospital, including the NICU and general oncology wards, using

standard infection control techniques. As a precautionary measure, people recently vaccinated with LAIV should restrict contact with severely immunocompromised patients for up to 7 days after immunization, although there have been no reports of LAIV transmission from a vaccinated person to an immunocompromised person. In the theoretical scenario in which symptomatic LAIV infection develops in an immunocompromised host, oseltamivir or zanamivir could be prescribed, because LAIV strains are susceptible to these antiviral medications.

SURVEILLANCE

Information about influenza surveillance is available through the CDC Voice Information System (influenza update, 888-232-3228) or at www.cdc.gov/flu/index.htm. Although current influenza season data on circulating strains do not necessarily predict which and in what proportion strains will circulate in the subsequent season, it is instructive to be aware of 2013–2014 influenza surveillance data and use them as a guide to empirical therapy until current seasonal data are available from the CDC. Information is posted weekly on the CDC Web site (www.cdc.gov/flu/weekly/fluactivity.htm).

VACCINE IMPLEMENTATION

These updated recommendations for prevention and control of influenza in children will have operational and fiscal effects on pediatric practice. Therefore, the AAP has developed implementation guidance on supply, payment, coding, and liability issues; these documents can be found at www.aapredbook.org/implementation. In addition, the AAP's Partnership for Policy Implementation has developed a series of definitions using accepted health information technology standards to assist in the implementation

of this guideline in computer systems and quality measurement efforts. This document is available at www2.aap.org/informatics/PPI.html.

USE OF ANTIVIRAL MEDICATIONS

Oral oseltamivir remains the antiviral drug of choice for the management of influenza infections. Inhaled zanamivir is an equally acceptable alternative but is more difficult to administer. Antiviral resistance can emerge quickly between seasons. If local or national influenza surveillance data indicate a predominance of a particular influenza strain with a known antiviral susceptibility profile, then empirical treatment can be directed toward that strain. For example, all the influenza A (H3N2) and influenza B viruses tested since October 1, 2013 were sensitive to oseltamivir and zanamivir during the 2013–2014 influenza season. Among the pH1N1 viruses tested for resistance, only 1.2% were found to be resistant to oseltamivir, and none were found to be resistant to zanamivir. In contrast, high levels of resistance to amantadine and rimantadine exist, so these drugs should not be used in the upcoming season unless resistance patterns change significantly.

- Current treatment guidelines for antiviral medications (Table 3) are applicable to both infants and children with suspected influenza when known virus strains are circulating in the community or when infants or children are confirmed to have seasonal influenza.
- Oseltamivir is available in capsule and oral suspension formulations. The commercially manufactured liquid formulation has a concentration of 6 mg/mL. If the commercially manufactured oral suspension is not available, the capsule may be opened and the contents mixed with simple syrup or Oral-Sweet

SF (sugar-free) by retail pharmacies to a final concentration of 6 mg/mL (Table 3).

- Continuous monitoring of the epidemiology, change in severity, and resistance patterns of influenza strains may lead to new guidance.

Treatment should be offered for:

- Any child hospitalized with presumed influenza or with severe, complicated, or progressive illness attributable to influenza, regardless of influenza immunization status or whether onset of illness occurred >48 hours before admission.
- Influenza infection of any severity in children at high risk of complications of influenza infection (Table 4), such as children younger than 2 years.

Treatment should be considered for:

- Any otherwise healthy child with influenza infection for whom a decrease in duration of clinical symptoms is felt to be warranted by his or her pediatrician. The greatest impact on outcome will occur if treatment can be initiated within 48 hours of illness onset but still should be considered if later in the course of illness.

Reviews of available studies by the CDC, the World Health Organization, and independent investigators have consistently found that timely oseltamivir treatment can reduce the risks of complications, including those resulting in hospitalization and death. Although a 2012 Cochrane review of studies primarily in outpatient settings suggested that oseltamivir may not be effective in preventing complications or hospitalizations from influenza, its authors correctly pointed out that the data reviewed were not always complete, were analyzed in a variety of treated populations, and used a number of clinical trial designs. In addition, a recently revised 2014 Cochrane

review of NAIs for influenza further evaluated published and previously unpublished data from randomized clinical trials largely in healthy outpatients with mild illness. Unlike other analyses of the efficacy of antiviral drugs, this Cochrane analysis included both influenza virus–infected and noninfected people with influenza-like illness. Given the specific antiviral activity of NAIs against influenza viruses, this analytic approach underestimates the treatment efficacy of NAIs and their valuable role in helping to lessen complications in those at high risk for them, including hospitalized patients. Furthermore, this review of outpatients was not designed

to assess the effect on severe outcomes such as hospitalizations or deaths.

Importantly, treatment with oseltamivir for children with presumed serious, complicated, or progressive disease, irrespective of influenza immunization status or even whether illness began greater than 48 hours before admission, continues to be recommended by the AAP, CDC, and Infectious Diseases Society of America (IDSA) (http://www.idsociety.org/Influenza_Statement.aspx). Earlier treatment provides better clinical responses. However, treatment after 48 hours of symptoms in adults and children with moderate to severe disease or with progressive disease has

been shown to provide some benefit and should be strongly considered. In previous years, the use of double-dose oseltamivir, particularly for those hospitalized with severe illness caused by pH1N1, was believed to provide better outcomes. However, recently published data from a randomized, prospective trial with 75% of subjects younger than 15 years documented no benefit of double-dose therapy over standard-dose therapy.

Dosages for antiviral agents for both treatment and chemoprophylaxis in children can be found in Table 3 and on the CDC Web site (<http://www.cdc.gov/flu/professionals/antivirals/index.htm>). Children younger than 2 years

TABLE 3 Recommended Dosage and Schedule of Influenza Antiviral Medications for Treatment and Chemoprophylaxis for the 2014–2015 Influenza Season: United States

Medication	Treatment (5 d)	Chemoprophylaxis (10 d)
Oseltamivir^a		
Adults	75 mg twice daily	75 mg once daily
Children ≥12 mo		
Body wt		
≤15 kg (≤33 lb)	30 mg twice daily	30 mg once daily
>15–23 kg (33–51 lb)	45 mg twice daily	45 mg once daily
>23–40 kg (51–88 lb)	60 mg twice daily	60 mg once daily
>40 kg (>88 lb)	75 mg twice daily	75 mg once daily
Infants 9–11 mo ^b	3.5 mg/kg per dose twice daily	3.5 mg/kg per dose once daily
Term infants 0–8 mo ^b	3 mg/kg per dose twice daily	3 mg/kg per dose once daily for infants 3–8 mo; not recommended for infants <3 mo, unless situation judged critical, because of limited safety and efficacy data in this age group
Preterm infants	See details in footnote ^c	
Zanamivir^d		
Adults	10 mg (two 5-mg inhalations) twice daily	10 mg (two 5-mg inhalations) once daily
Children (≥7 y for treatment, ≥5 y for chemoprophylaxis)	10 mg (two 5-mg inhalations) twice daily	10 mg (two 5-mg inhalations) once daily

Sources: Centers for Disease Control and Prevention. Antiviral agents for the treatment and chemoprophylaxis of influenza: recommendations of the Advisory Committee on Immunization Practices (ACIP). *MMWR Recomm Rep*. 2011;60(RR-1):1–24; Kimberlin DW, Acosta EP, Prichard MN, et al. National Institute of Allergy and Infectious Diseases Collaborative Antiviral Study Group. Oseltamivir pharmacokinetics, dosing, and resistance among children aged <2 y with influenza. *J Infect Dis*. 2013;207(5):709–720.

^a Oseltamivir is administered orally without regard to meals, although administration with meals may improve gastrointestinal tolerability. Oseltamivir is available as Tamiflu in 30-mg, 45-mg, and 75-mg capsules and as a powder for oral suspension that is reconstituted to provide a final concentration of 6 mg/mL. For the 6-mg/mL suspension, a 30-mg dose is given with 5 mL of oral suspension, a 45-mg dose is given with 7.5 mL oral suspension, a 60-mg dose is given with 10 mL oral suspension, and a 75-mg dose is given with 12.5 mL oral suspension. If the commercially manufactured oral suspension is not available, a suspension can be compounded by retail pharmacies (final concentration also 6 mg/mL), based on instructions that are present on the package label. In patients with renal insufficiency, the dose should be adjusted on the basis of creatinine clearance. For treatment of patients with creatinine clearance 10–30 mL/min, administer 75 mg, once daily, for 5 d. For chemoprophylaxis of patients with creatinine clearance 10–30 mL/min, administer 30 mg, once daily, for 10 d after exposure or 75 mg, once every other day, for 10 d after exposure (5 doses). See <http://www.cdc.gov/flu/professionals/antivirals/antiviral-drug-resistance.htm>.

^b Approved by the FDA for children as young as 2 wk of age. Given preliminary pharmacokinetic data and limited safety data, oseltamivir can be used to treat influenza in both term and preterm infants from birth because benefits of therapy are likely to outweigh possible risks of treatment.

^c Oseltamivir dosing for preterm infants. The weight-based dosing recommendation for preterm infants is lower than for term infants. Preterm infants may have lower clearance of oseltamivir because of immature renal function, and doses recommended for full-term infants may lead to very high drug concentrations in this age group. Limited data from the National Institute of Allergy and Infectious Diseases Collaborative Antiviral Study Group provide the basis for dosing preterm infants using their postmenstrual age (gestational age + chronological age): 1.0 mg/kg per dose, orally, twice daily, for those <38 wk postmenstrual age; 1.5 mg/kg per dose, orally, twice daily, for those 38 through 40 wk postmenstrual age; 3.0 mg/kg per dose, orally, twice daily, for those >40 wk postmenstrual age. For extremely premature infants (<28 wk postmenstrual age), consult a pediatric infectious disease physician.

^d Zanamivir is administered by inhalation using a proprietary “Diskhaler” device distributed together with the medication. Zanamivir is a dry powder, not an aerosol, and should not be administered with nebulizers, ventilators, or other devices typically used to administer medications in aerosolized solutions. Zanamivir is not recommended for people with chronic respiratory diseases, such as asthma or chronic obstructive pulmonary disease, which increase the risk of bronchospasm.

TABLE 4 People at Higher Risk of Influenza Complications Recommended for Antiviral Treatment of Suspected or Confirmed Influenza

Children <2 y
Adults ≥65 y
People with chronic pulmonary (including asthma), cardiovascular (except hypertension alone), renal, hepatic, hematologic (including sickle cell disease), or metabolic disorders (including diabetes mellitus) or neurologic and neurodevelopment conditions (including disorders of the brain, spinal cord, peripheral nerve, and muscle such as cerebral palsy, epilepsy [seizure disorders], stroke, intellectual disability [mental retardation], moderate to severe developmental delay, muscular dystrophy, or spinal cord injury)
People with immunosuppression, including that caused by medications or by HIV infection
Women who are pregnant or postpartum (within 2 wk after delivery)
People <19 y who are receiving long-term aspirin therapy
American Indian or Alaska Native people
People who are morbidly obese (ie, BMI ≥40)
Residents of nursing homes and other chronic care facilities

Source: Centers for Disease Control and Prevention. Antiviral agents for the treatment and chemoprophylaxis of influenza: recommendations of the Advisory Committee on Immunization Practices (ACIP). *MMWR Recomm Rep*. 2011;60(RR-1):1–24.

are at elevated risk of hospitalization and complications attributable to influenza. The FDA has licensed oseltamivir for children as young as 2 weeks of age. Given preliminary pharmacokinetic data and limited safety data, oseltamivir can be used to treat influenza in both term and preterm infants from birth because benefits of therapy are likely to outweigh possible risks of treatment.

Clinical judgment (on the basis of underlying conditions, disease severity, time since symptom onset, and local influenza activity) is an important factor in treatment decisions for pediatric patients who present with influenza-like illness. Antiviral treatment should be started as soon as possible after illness onset and should not be delayed while waiting for a definitive influenza test result because early therapy provides the best outcomes. Recently available rapid antigen tests have moderate sensitivity, even for the pH1N1 virus strain, but are not as sensitive as nucleic acid–based molecular diagnostic techniques (eg, polymerase chain reaction [PCR] assay). Decisions on treatment and infection control can be made based on positive rapid antigen tests. However, if rapid test results are negative, PCR techniques should be considered, because they have greater sensitivity for influenza infection than

antigen tests. Positive results are helpful, because they may reduce additional testing to identify the cause of the child's influenza-like illness. Treatment should not be withheld in high-risk patients awaiting PCR results.

People with suspected influenza who present with an uncomplicated febrile illness typically do not need treatment with antiviral medications unless they are at higher risk of influenza complications (eg, children with chronic medical conditions such as asthma, diabetes mellitus, hemodynamically significant cardiac disease, immunosuppression, or neurologic and neurodevelopmental disorders), especially in situations with limited antiviral medication availability. Antiviral treatment also should be considered for symptomatic siblings of children younger than 6 months or with underlying medical conditions that predispose them to complications of influenza. If there is a shortage of antiviral medications, local public health authorities should provide additional guidance about testing and treatment. In past years, local shortages have occurred based on uneven drug distribution, but national shortages have not occurred.

Randomized placebo-controlled studies showed that oseltamivir and zanamivir were efficacious when ad-

ministered as chemoprophylaxis to household contacts after a family member had laboratory-confirmed influenza. During the 2009 pandemic, the emergence of oseltamivir resistance was observed among people receiving postexposure prophylaxis. Decisions on whether to administer antiviral chemoprophylaxis should take into account the exposed person's risk of influenza complications, vaccination status, the type and duration of contact, recommendations from local or public health authorities, and clinical judgment. Optimally, postexposure chemoprophylaxis should only be used when antiviral agents can be started within 48 hours of exposure. Early treatment of high-risk patients without waiting for laboratory confirmation is an alternative strategy.

Although immunization is the preferred approach to infection prevention, chemoprophylaxis during an influenza outbreak, as defined by the CDC, is recommended

- For children at high risk of complications from influenza for whom influenza vaccine is contraindicated
- For children at high risk during the 2 weeks after influenza immunization
- For family members or HCP who are unimmunized and are likely to have ongoing, close exposure to
 - Unimmunized children at high risk
 - Unimmunized infants and toddlers who are younger than 24 months
- For control of influenza outbreaks for unimmunized staff and children in a closed institutional setting with children at high risk (eg, extended-care facilities)
- As a supplement to immunization among children at high risk, including children who are immunocompromised and may not respond to vaccine

- As postexposure prophylaxis for family members and close contacts of an infected person if those people are at high risk of complications from influenza
- For children at high risk and their family members and close contacts, as well as HCP, when circulating strains of influenza virus in the community are not matched with seasonal influenza vaccine strains, on the basis of current data from the CDC and local health departments

These recommendations apply to routine circumstances, but it should be noted that guidance may change on the basis of updated recommendations from the CDC in concert with antiviral availability, local resources, clinical judgment, recommendations from local or public health authorities, risk of influenza complications, type and duration of exposure contact, and change in epidemiology or severity of influenza. Chemoprophylaxis is not recommended for infants younger than 3 months, unless the situation is judged critical, because of limited safety and efficacy data in this age group.

Chemoprophylaxis Should Not Be Considered a Substitute for Immunization

Influenza vaccine should always be offered when not contraindicated, even after influenza virus has been circulating in the community. Antiviral medications currently licensed are important adjuncts to influenza immunization for control and prevention of influenza disease; toxicities associated with antiviral agents or indiscriminate use might limit availability. Pediatricians should inform recipients of antiviral chemoprophylaxis that risk of influenza is lowered but still remains while they are taking the medication, and susceptibility to influenza returns when medication is discontinued.

Oseltamivir use is not a contraindication to immunization with IIV (unlike LAIV). For recommendations about treatment and chemoprophylaxis against influenza, see Table 3. Among some high-risk people, both vaccination and antiviral chemoprophylaxis may be considered. Updates will be available at www.aapredbook.org/flu and www.cdc.gov/flu/professionals/antivirals/index.htm.

FUTURE NEEDS

For the 2014–2015 season, the AAP does not have a preferential recommendation for any type or brand of influenza vaccine over another. This is partly because the supply and distribution of newer vaccines may be limited during the 2014–2015 season. Moreover, post-marketing safety and vaccine effectiveness data are limited, precluding a full risk–benefit analysis of newer versus previously available products. However, such analyses will be performed as data become available, and in the future specific vaccines may be preferentially recommended for particular groups.

A large body of evidence indicates that even children with severe (anaphylactic) allergic reactions to the ingestion of eggs tolerate IIV in a single, age-appropriate dose. If, as expected, safety monitoring continues to show no elevated risk for anaphylactic reactions in egg-allergic recipients of IIV, special precautions regarding allergy consultation and waiting periods after administration to egg-allergic recipients beyond those recommended for any vaccine may no longer be recommended. Studies examining the safety of LAIV in egg-allergic recipients also are ongoing.

Efforts should be made to create adequate outreach and infrastructure to facilitate the optimal distribution of vaccine so that more people are immunized. Pediatricians also should become more involved in pandemic preparedness or disaster planning

efforts. A bidirectional partner dialogue between pediatricians and public health decision makers assists efforts to address children's issues during the initial state, regional, and local plan development stages. Additional information about disaster preparedness can be found at www.aap.org/en-us/advocacy-and-policy/aap-health-initiatives/children-and-disasters/Pages/Pediatric-Preparedness-Resource-Kit.aspx.

Health care for children is best provided in the medical home, which may have limited capacity to accommodate all patients (and their families) seeking influenza immunization. With the greater demand for immunization during each influenza season, the AAP and the CDC recommend vaccine administration at any visit to the medical home during influenza season when it is not contraindicated, at specially arranged vaccine-only sessions, and through cooperation with community sites, schools, and child care centers to provide influenza vaccine. If alternative venues, including pharmacies and other retail-based clinics, are used for immunization, a system of patient record transfer is beneficial in maintaining the accuracy of immunization records. Immunization information systems should be used whenever available. Two-dimensional barcodes have been used to facilitate more efficient and accurate documentation of vaccine administration, with limited experience to date. Multiple barriers appear to affect influenza vaccination coverage for children in foster care, refugee and immigrant children, and homeless children. Access to care issues, lack of immunization records, and questions about who can provide consent may be addressed by linking children with a medical home, using all health care encounters as vaccination opportunities, and more consistently using immunization registry data.

Cost-effectiveness and logistic feasibility of vaccinating everyone continue to be concerns. With universal immunization, particular attention is being paid to vaccine supply, distribution, implementation, and financing. Potential benefits of more widespread childhood immunization among recipients, their contacts, and the community include fewer influenza cases, fewer outpatient visits and hospitalizations for influenza infection, and a decrease in the use of antimicrobial agents, absenteeism from school, and lost parent work time. To administer antiviral therapy optimally in hospitalized patients with influenza who cannot tolerate oral or inhaled antiviral agents, FDA-approved intravenous NAIs for children also are needed.

Continued evaluation of the safety, immunogenicity, and effectiveness of influenza vaccine, especially for children younger than 2 years, is important. The potential role of previous influenza vaccination on overall vaccine effectiveness by virus strain and subject age in preventing outpatient medical visits, hospitalizations, and deaths continues to be evaluated. Continued assessment of the safety of LAIV is warranted as more children receive the vaccine annually. In addition, the routine use of LAIV in children with certain respiratory and nonrespiratory chronic medical conditions warrants additional consideration. There is also a need for more systematic health service research on influenza vaccine uptake and refusal as well as identification of methods to increase uptake. In addition, development of a safe, immunogenic vaccine for infants younger than 6 months is essential. Until such a vaccine is available for infants younger than 6 months, vaccination of their mothers during pregnancy is the best way to protect these infants. Breast-feeding also is recommended to protect against influenza viruses by activating

innate antiviral mechanisms, specifically type 1 interferons. Mandatory annual influenza immunization of all HCP has been implemented successfully at an increasing number of pediatric institutions. Future efforts should include broader implementation of mandatory immunization programs. Optimal prevention of influenza in the health care setting depends on the vaccination of at least 90% of HCP. Additional studies are needed to investigate the extent of offering to immunize parents and adult child care providers in the pediatric office setting; the level of family contact satisfaction with this practice; how practices handle the logistic, liability, legal, and financial barriers that limit or complicate this service; and, most importantly, how this practice will affect disease rates in children and adults. In addition, adjuvants have been shown to increase immune responses to influenza vaccines, but certain adjuvants have been associated with the development of narcolepsy in some studies. Additional studies on the effectiveness and safety of influenza vaccines containing adjuvants are needed. Finally, efforts to improve the vaccine development process to allow a shorter interval between identification of vaccine strains and vaccine production continue.

The 2015 recommended childhood and adolescent immunization schedule has been approved by the American Academy of Pediatrics, the Advisory Committee on Immunization Practices of the Centers for Disease Control and Prevention, the American Academy of Family Physicians, and the American College of Obstetricians and Gynecologists. The 2015 format is similar to last year and includes a single schedule for people birth through 18 years of age. The yellow bars indicate the recommended age range for all children and contain a notation indicating the recommended dose number by age. The green bars indicate the recommended catch-up age. The purple bars designate the range for immunization for certain groups at high risk. The combined green and purple bar indicates the recommended age when hepatitis A vaccine catch-up is recommended. The white boxes show the ages when a vaccine is not recommended routinely. The catch-up schedule offers recommendations for children and adolescents 4 months through 18 years of age who start late or are >1 month behind.

Unlike previous years, the immunization schedules will not be published in *Pediatrics*. Readers are referred to the American Academy of Pediatrics Web site (http://redbook.solutions.aap.org/SS/Immunization_Schedules.aspx) or the Centers for Disease Control and Prevention Web site (<http://www.cdc.gov/vaccines/schedules/hcp/child-adolescent.html>) for the most recent edition of the immunization schedule, the full set of footnotes, and the catch-up schedule. This will ensure providers have the most current recommendations. The online schedule will be updated when new vaccines are licensed and recommendations for use are established and when a change is made to a recommendation for use of an existing vaccine. In addition, the Web site includes tables (job-aids) to assist in clarification of recommended use of *Haemophilus influenzae* type b, pneumococcal, and pertussis-containing vaccines as a function of age, the number of doses previously administered, and the time interval since the last dose.

Footnotes contain recommendations for routine vaccination, for catch-up vaccination, and for vaccination of children and adolescents with high-risk

conditions or in special circumstances. A parent-friendly vaccine schedule for children and adolescents is available at <http://www.cdc.gov/vaccines/schedules/index.html>.

An adult immunization schedule is published in February of each year and is available at www.cdc.gov/vaccines.

These schedules are revised annually to reflect current recommendations for the use of vaccines licensed by the US Food and Drug Administration and include the following specific changes from last year:

- A column has been added to the immunization schedule at 2 through 8 years to emphasize the availability of inactivated influenza vaccine and live-attenuated influenza vaccine starting at 2 years of age, as well as the need for 2 doses for some children in this age group. A second column has been added at 9 through 10 years to indicate when 2 doses are no longer needed. In addition, a purple bar has been added for young children 6 months to less than 12 months traveling outside the United States and who will need measles mumps rubella vaccine.
- Minor, clarifying word changes were made to the catch-up schedule with regard to *Haemophilus influenzae* type b; pneumococcal conjugate; tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis, adsorbed; hepatitis A; hepatitis B; polio; meningococcal; measles mumps rubella; and varicella vaccines.
- Minor, simplifying word changes were made to the footnotes relating

to diphtheria-tetanus-acellular pertussis and pneumococcal conjugate vaccines. The influenza vaccine footnote was updated to reflect revised contraindications and precautions for the live-attenuated influenza vaccine. The meningococcal footnote underwent extensive revision to clarify appropriate dosing schedules for high-risk infants and children for the 3 different vaccines.

Clinically significant adverse events that follow immunization should be reported to the Vaccine Adverse Event Reporting System. Guidance about how to obtain and complete a Vaccine Adverse Event Reporting System form can be obtained at www.vaers.hhs.gov or by calling 800-822-7967. Additional information can be found in the *Red Book* and at *Red Book Online* (<http://redbook.solutions.aap.org/redbook.aspx>). Statements from the Advisory Committee on Immunization Practices of the Centers for Disease Control and Prevention that contain details of recommendations for individual vaccines, including recommendations for children with high-risk conditions, are available at www.cdc.gov/vaccines/pubs/ACIP-list.htm. Information on new vaccine releases, vaccine supplies, and interim recommendations resulting from vaccine shortages and statements on specific vaccines can be found at <http://redbook.solutions.aap.org/vaccine-status.aspx?gbosid=167073> and www.cdc.gov/vaccines/pubs/ACIP-list.htm.

Figure 1. Recommended immunization schedule for persons aged 0 through 18 years – United States, 2015.**(FOR THOSE WHO FALL BEHIND OR START LATE, SEE THE CATCH-UP SCHEDULE [FIGURE 2]).**

These recommendations must be read with the footnotes that follow. For those who fall behind or start late, provide catch-up vaccination at the earliest opportunity as indicated by the green bars in Figure 1. To determine minimum intervals between doses, see the catch-up schedule (Figure 2). School entry and adolescent vaccine age groups are shaded.

Vaccine	Birth	1 mo	2 mos	4 mos	6 mos	9 mos	12 mos	15 mos	18 mos	19–23 mos	2–3 yrs	4–6 yrs	7–10 yrs	11–12 yrs	13–15 yrs	16–18 yrs
Hepatitis B ¹ (HepB)	1 st dose	←----- 2 nd dose -----→			←----- 3 rd dose -----→											
Rotavirus ² (RV) RV1 (2-dose series); RV5 (3-dose series)			1 st dose	2 nd dose	See footnote 2											
Diphtheria, tetanus, & acellular pertussis ³ (DTaP: <7 yrs)			1 st dose	2 nd dose	3 rd dose			←----- 4 th dose -----→				5 th dose				
Tetanus, diphtheria, & acellular pertussis ⁴ (Tdap: ≥7 yrs)														(Tdap)		
<i>Haemophilus influenzae</i> type b ⁵ (Hib)			1 st dose	2 nd dose	See footnote 5		←----- 3 rd or 4 th dose -----→ See footnote 5									
Pneumococcal conjugate ⁶ (PCV13)			1 st dose	2 nd dose	3 rd dose		←----- 4 th dose -----→									
Pneumococcal polysaccharide ⁶ (PPSV23)																
Inactivated poliovirus ⁷ (IPV: <18 yrs)			1 st dose	2 nd dose	←----- 3 rd dose -----→							4 th dose				
Influenza ⁸ (IIV; LAIV) 2 doses for some: See footnote 8					Annual vaccination (IIV only) 1 or 2 doses						Annual vaccination (LAIV or IIV) 1 or 2 doses		Annual vaccination (LAIV or IIV) 1 dose only			
Measles, mumps, rubella ⁹ (MMR)					See footnote 9		←----- 1 st dose -----→					2 nd dose				
Varicella ¹⁰ (VAR)							←----- 1 st dose -----→					2 nd dose				
Hepatitis A ¹¹ (HepA)							←----- 2-dose series, See footnote 11 -----→									
Human papillomavirus ¹² (HPV2: females only; HPV4: males and females)														(3-dose series)		
Meningococcal ¹³ (Hib-MenCY ≥ 6 weeks; MenACWY-D ≥ 9 mos; MenACWY-CRM ≥ 2 mos)			See footnote 13											1 st dose		Booster

Range of recommended ages for all children

Range of recommended ages for catch-up immunization

Range of recommended ages for certain high-risk groups

Range of recommended ages during which catch-up is encouraged and for certain high-risk groups

Not routinely recommended

This schedule includes recommendations in effect as of January 1, 2015. Any dose not administered at the recommended age should be administered at a subsequent visit, when indicated and feasible. The use of a combination vaccine generally is preferred over separate injections of its equivalent component vaccines. Vaccination providers should consult the relevant Advisory Committee on Immunization Practices (ACIP) statement for detailed recommendations, available online at <http://www.cdc.gov/vaccines/hcp/acip-recs/index.html>. Clinically significant adverse events that follow vaccination should be reported to the Vaccine Adverse Event Reporting System (VAERS) online (<http://www.vaers.hhs.gov>) or by telephone (800-822-7967). Suspected cases of vaccine-preventable diseases should be reported to the state or local health department. Additional information, including precautions and contraindications for vaccination, is available from CDC online (<http://www.cdc.gov/vaccines/recs/vac-admin/contraindications.htm>) or by telephone (800-CDC-INFO [800-232-4636]).

This schedule is approved by the Advisory Committee on Immunization Practices (<http://www.cdc.gov/vaccines/acip>), the American Academy of Pediatrics (<http://www.aap.org>), the American Academy of Family Physicians (<http://www.aafp.org>), and the American College of Obstetricians and Gynecologists (<http://www.acog.org>).

NOTE: The above recommendations must be read along with the footnotes of this schedule.

FIGURE 2. Catch-up immunization schedule for persons aged 4 months through 18 years who start late or who are more than 1 month behind —United States, 2015.

The figure below provides catch-up schedules and minimum intervals between doses for children whose vaccinations have been delayed. A vaccine series does not need to be restarted, regardless of the time that has elapsed between doses. Use the section appropriate for the child's age. Always use this table in conjunction with Figure 1 and the footnotes that follow.

Children age 4 months through 6 years					
Vaccine	Minimum Age for Dose 1	Minimum Interval Between Doses			
		Dose 1 to Dose 2	Dose 2 to Dose 3	Dose 3 to Dose 4	Dose 4 to Dose 5
Hepatitis B ¹	Birth	4 weeks	8 weeks and at least 16 weeks after first dose. Minimum age for the final dose is 24 weeks.		
Rotavirus ²	6 weeks	4 weeks	4 weeks ²		
Diphtheria, tetanus, and acellular pertussis ³	6 weeks	4 weeks	4 weeks	6 months	6 months ³
<i>Haemophilus influenzae</i> type b ⁵	6 weeks	4 weeks if first dose was administered before the 1 st birthday. 8 weeks (as final dose) if first dose was administered at age 12 through 14 months. No further doses needed if first dose was administered at age 15 months or older.	4 weeks ⁵ if current age is younger than 12 months and first dose was administered at younger than age 7 months, and at least 1 previous dose was PRP-T (ActHib, Pentacel) or unknown. 8 weeks and age 12 through 59 months (as final dose) ⁵ • if current age is younger than 12 months and first dose was administered at age 7 through 11 months; OR • if current age is 12 through 59 months and first dose was administered before the 1 st birthday, and second dose administered at younger than 15 months; OR • if both doses were PRP-OMP (PedvaxHIB; Comvax) and were administered before the 1 st birthday. No further doses needed if previous dose was administered at age 15 months or older.	8 weeks (as final dose) This dose only necessary for children age 12 through 59 months who received 3 doses before the 1 st birthday.	
Pneumococcal ⁶	6 weeks	4 weeks if first dose administered before the 1 st birthday. 8 weeks (as final dose for healthy children) if first dose was administered at the 1 st birthday or after. No further doses needed for healthy children if first dose administered at age 24 months or older.	4 weeks if current age is younger than 12 months and previous dose given at <7months old. 8 weeks (as final dose for healthy children) if previous dose given between 7-11 months (wait until at least 12 months old); OR if current age is 12 months or older and at least 1 dose was given before age 12 months. No further doses needed for healthy children if previous dose administered at age 24 months or older.	8 weeks (as final dose) This dose only necessary for children aged 12 through 59 months who received 3 doses before age 12 months or for children at high risk who received 3 doses at any age.	
Inactivated poliovirus ⁷	6 weeks	4 weeks ⁷	4 weeks ⁷	6 months ⁷ (minimum age 4 years for final dose).	
Meningococcal ¹³	6 weeks	8 weeks ¹³	See footnote 13	See footnote 13	
Measles, mumps, rubella ⁹	12 months	4 weeks			
Varicella ¹⁰	12 months	3 months			
Hepatitis A ¹¹	12 months	6 months			
Children and adolescents age 7 through 18 years					
Tetanus, diphtheria; tetanus, diphtheria, and acellular pertussis ⁴	7 years ⁴	4 weeks	4 weeks if first dose of DTaP/DT was administered before the 1 st birthday. 6 months (as final dose) if first dose of DTaP/DT was administered at or after the 1 st birthday.	6 months if first dose of DTaP/DT was administered before the 1 st birthday.	
Human papillomavirus ¹²	9 years	Routine dosing intervals are recommended. ¹²			
Hepatitis A ¹¹	Not applicable (N/A)	6 months			
Hepatitis B ¹	N/A	4 weeks	8 weeks and at least 16 weeks after first dose.		
Inactivated poliovirus ⁷	N/A	4 weeks	4 weeks ⁷	6 months ⁷	
Meningococcal ¹³	N/A	8 weeks ¹³			
Measles, mumps, rubella ⁹	N/A	4 weeks			
Varicella ¹⁰	N/A	3 months if younger than age 13 years. 4 weeks if age 13 years or older.			

NOTE: The above recommendations must be read along with the footnotes of this schedule.

Footnotes — Recommended immunization schedule for persons aged 0 through 18 years—United States, 2015

For further guidance on the use of the vaccines mentioned below, see: <http://www.cdc.gov/vaccines/hcp/acip-recs/index.html>.

For vaccine recommendations for persons 19 years of age and older, see the Adult Immunization Schedule.

Additional information

- For contraindications and precautions to use of a vaccine and for additional information regarding that vaccine, vaccination providers should consult the relevant ACIP statement available online at <http://www.cdc.gov/vaccines/hcp/acip-recs/index.html>.
- For purposes of calculating intervals between doses, 4 weeks = 28 days. Intervals of 4 months or greater are determined by calendar months.
- Vaccine doses administered 4 days or less before the minimum interval are considered valid. Doses of any vaccine administered ≥ 5 days earlier than the minimum interval or minimum age should not be counted as valid doses and should be repeated as age-appropriate. The repeat dose should be spaced after the invalid dose by the recommended minimum interval. For further details, see *MMWR, General Recommendations on Immunization and Reports* / Vol. 60 / No. 2; Table 1. *Recommended and minimum ages and intervals between vaccine doses* available online at <http://www.cdc.gov/mmwr/pdf/rr/rr6002.pdf>.
- Information on travel vaccine requirements and recommendations is available at <http://www.wnc.cdc.gov/travel/destinations/list>.
- For vaccination of persons with primary and secondary immunodeficiencies, see Table 13, "Vaccination of persons with primary and secondary immunodeficiencies," in *General Recommendations on Immunization* (ACIP), available at <http://www.cdc.gov/mmwr/pdf/rr/rr6002.pdf>; and American Academy of Pediatrics. "Immunization in Special Clinical Circumstances," in Pickering LK, Baker CJ, Kimberlin DW, Long SS eds. *Red Book: 2012 report of the Committee on Infectious Diseases*. 29th ed. Elk Grove Village, IL: American Academy of Pediatrics.

1. Hepatitis B (HepB) vaccine. (Minimum age: birth)

Routine vaccination:

At birth:

- Administer monovalent HepB vaccine to all newborns before hospital discharge.
- For infants born to hepatitis B surface antigen (HBsAg)-positive mothers, administer HepB vaccine and 0.5 mL of hepatitis B immune globulin (HBIG) within 12 hours of birth. These infants should be tested for HBsAg and antibody to HBsAg (anti-HBs) 1 to 2 months after completion of the HepB series at age 9 through 18 months (preferably at the next well-child visit).
- If mother's HBsAg status is unknown, within 12 hours of birth administer HepB vaccine regardless of birth weight. For infants weighing less than 2,000 grams, administer HBIG in addition to HepB vaccine within 12 hours of birth. Determine mother's HBsAg status as soon as possible and, if mother is HBsAg-positive, also administer HBIG for infants weighing 2,000 grams or more as soon as possible, but no later than age 7 days.

Doses following the birth dose:

- The second dose should be administered at age 1 or 2 months. Monovalent HepB vaccine should be used for doses administered before age 6 weeks.
- Infants who did not receive a birth dose should receive 3 doses of a HepB-containing vaccine on a schedule of 0, 1 to 2 months, and 6 months starting as soon as feasible. See Figure 2.
- Administer the second dose 1 to 2 months after the first dose (minimum interval of 4 weeks), administer the third dose at least 8 weeks after the second dose AND at least 16 weeks after the **first** dose. The final (third or fourth) dose in the HepB vaccine series should be administered **no earlier than age 24 weeks**.
- Administration of a total of 4 doses of HepB vaccine is permitted when a combination vaccine containing HepB is administered after the birth dose.

Catch-up vaccination:

- Unvaccinated persons should complete a 3-dose series.
- A 2-dose series (doses separated by at least 4 months) of adult formulation Recombivax HB is licensed for use in children aged 11 through 15 years.
- For other catch-up guidance, see Figure 2.

2. Rotavirus (RV) vaccines. (Minimum age: 6 weeks for both RV1 [Rotarix] and RV5 [RotaTeq])

Routine vaccination:

Administer a series of RV vaccine to all infants as follows:

- If Rotarix is used, administer a 2-dose series at 2 and 4 months of age.
- If RotaTeq is used, administer a 3-dose series at ages 2, 4, and 6 months.
- If any dose in the series was RotaTeq or vaccine product is unknown for any dose in the series, a total of 3 doses of RV vaccine should be administered.

Catch-up vaccination:

- The maximum age for the first dose in the series is 14 weeks, 6 days; vaccination should not be initiated for infants aged 15 weeks, 0 days or older.
- The maximum age for the final dose in the series is 8 months, 0 days.
- For other catch-up guidance, see Figure 2.

3. Diphtheria and tetanus toxoids and acellular pertussis (DTaP) vaccine. (Minimum age: 6 weeks. Exception: DTaP-IPV [Kinrix]: 4 years)

Routine vaccination:

- Administer a 5-dose series of DTaP vaccine at ages 2, 4, 6, 15 through 18 months, and 4 through 6 years. The fourth dose may be administered as early as age 12 months, provided at least 6 months have elapsed since the third dose. However, the fourth dose of DTaP need not be repeated if it was administered at least 4 months after the third dose of DTaP.

3. Diphtheria and tetanus toxoids and acellular pertussis (DTaP) vaccine (cont'd)

Catch-up vaccination:

- The fifth dose of DTaP vaccine is not necessary if the fourth dose was administered at age 4 years or older.
- For other catch-up guidance, see Figure 2.

4. Tetanus and diphtheria toxoids and acellular pertussis (Tdap) vaccine. (Minimum age: 10 years for both Boostrix and Adacel)

Routine vaccination:

- Administer 1 dose of Tdap vaccine to all adolescents aged 11 through 12 years.
- Tdap may be administered regardless of the interval since the last tetanus and diphtheria toxoid-containing vaccine.
- Administer 1 dose of Tdap vaccine to pregnant adolescents during each pregnancy (preferred during 27 through 36 weeks' gestation) regardless of time since prior Td or Tdap vaccination.

Catch-up vaccination:

- Persons aged 7 years and older who are not fully immunized with DTaP vaccine should receive Tdap vaccine as 1 dose (preferably the first) in the catch-up series; if additional doses are needed, use Td vaccine. For children 7 through 10 years who receive a dose of Tdap as part of the catch-up series, an adolescent Tdap vaccine dose at age 11 through 12 years should NOT be administered. Td should be administered instead 10 years after the Tdap dose.
- Persons aged 11 through 18 years who have not received Tdap vaccine should receive a dose followed by tetanus and diphtheria toxoid (Td) booster doses every 10 years thereafter.
- Inadvertent doses of DTaP vaccine:
 - If administered inadvertently to a child aged 7 through 10 years may count as part of the catch-up series. This dose may count as the adolescent Tdap dose, or the child can later receive a Tdap booster dose at age 11 through 12 years.
 - If administered inadvertently to an adolescent aged 11 through 18 years, the dose should be counted as the adolescent Tdap booster.
- For other catch-up guidance, see Figure 2.

5. *Haemophilus influenzae* type b (Hib) conjugate vaccine. (Minimum age: 6 weeks for PRP-T [ACTHIB, DTaP-IPV/Hib (Pentacel) and Hib-MenCY (MenHibrix)], PRP-OMP [PedvaxHIB or COMVAX], 12 months for PRP-T [Hiberix])

Routine vaccination:

- Administer a 2- or 3-dose Hib vaccine primary series and a booster dose (dose 3 or 4 depending on vaccine used in primary series) at age 12 through 15 months to complete a full Hib vaccine series.
- The primary series with ActHib, MenHibrix, or Pentacel consists of 3 doses and should be administered at 2, 4, and 6 months of age. The primary series with PedvaxHib or COMVAX consists of 2 doses and should be administered at 2 and 4 months of age; a dose at age 6 months is not indicated.
- One booster dose (dose 3 or 4 depending on vaccine used in primary series) of any Hib vaccine should be administered at age 12 through 15 months. An exception is Hiberix vaccine. Hiberix should only be used for the booster (final) dose in children aged 12 months through 4 years who have received at least 1 prior dose of Hib-containing vaccine.
- For recommendations on the use of MenHibrix in patients at increased risk for meningococcal disease, please refer to the meningococcal vaccine footnotes and also to *MMWR* February 28, 2014 / 63(RR01);1-13, available at <http://www.cdc.gov/mmwr/PDF/rr/rr6301.pdf>.

For further guidance on the use of the vaccines mentioned below, see: <http://www.cdc.gov/vaccines/hcp/acip-recs/index.html>.

5. *Haemophilus influenzae* type b (Hib) conjugate vaccine (cont'd)

Catch-up vaccination:

- If dose 1 was administered at ages 12 through 14 months, administer a second (final) dose at least 8 weeks after dose 1, regardless of Hib vaccine used in the primary series.
- If both doses were PRP-OMP (PedvaxHIB or COMVAX), and were administered before the first birthday, the third (and final) dose should be administered at age 12 through 59 months and at least 8 weeks after the second dose.
- If the first dose was administered at age 7 through 11 months, administer the second dose at least 4 weeks later and a third (and final) dose at age 12 through 15 months or 8 weeks after second dose, whichever is later.
- If first dose is administered before the first birthday and second dose administered at younger than 15 months, a third (and final) dose should be given 8 weeks later.
- For unvaccinated children aged 15 months or older, administer only 1 dose.
- For other catch-up guidance, see Figure 2. For catch-up guidance related to MenHibrix, please see the meningococcal vaccine footnotes and also *MMWR* February 28, 2014 / 63(RR01);1-13, available at <http://www.cdc.gov/mmwr/pdf/rr/rr6301.pdf>.

Vaccination of persons with high-risk conditions:

- Children aged 12 through 59 months who are at increased risk for Hib disease, including chemotherapy recipients and those with anatomic or functional asplenia (including sickle cell disease), human immunodeficiency virus (HIV) infection, immunoglobulin deficiency, or early component complement deficiency, who have received either no doses or only 1 dose of Hib vaccine before 12 months of age, should receive 2 additional doses of Hib vaccine 8 weeks apart; children who received 2 or more doses of Hib vaccine before 12 months of age should receive 1 additional dose.
- For patients younger than 5 years of age undergoing chemotherapy or radiation treatment who received a Hib vaccine dose(s) within 14 days of starting therapy or during therapy, repeat the dose(s) at least 3 months following therapy completion.
- Recipients of hematopoietic stem cell transplant (HSCT) should be revaccinated with a 3-dose regimen of Hib vaccine starting 6 to 12 months after successful transplant, regardless of vaccination history; doses should be administered at least 4 weeks apart.
- A single dose of any Hib-containing vaccine should be administered to unimmunized* children and adolescents 15 months of age and older undergoing an elective splenectomy; if possible, vaccine should be administered at least 14 days before procedure.
- Hib vaccine is not routinely recommended for patients 5 years or older. However, 1 dose of Hib vaccine should be administered to unimmunized* persons aged 5 years or older who have anatomic or functional asplenia (including sickle cell disease) and unvaccinated persons 5 through 18 years of age with human immunodeficiency virus (HIV) infection.

* Patients who have not received a primary series and booster dose or at least 1 dose of Hib vaccine after 14 months of age are considered unimmunized.

6. Pneumococcal vaccines. (Minimum age: 6 weeks for PCV13, 2 years for PPSV23)

Routine vaccination with PCV13:

- Administer a 4-dose series of PCV13 vaccine at ages 2, 4, and 6 months and at age 12 through 15 months.
- For children aged 14 through 59 months who have received an age-appropriate series of 7-valent PCV (PCV7), administer a single supplemental dose of 13-valent PCV (PCV13).

Catch-up vaccination with PCV13:

- Administer 1 dose of PCV13 to all healthy children aged 24 through 59 months who are not completely vaccinated for their age.
- For other catch-up guidance, see Figure 2.

Vaccination of persons with high-risk conditions with PCV13 and PPSV23:

- All recommended PCV13 doses should be administered prior to PPSV23 vaccination if possible.
- For children 2 through 5 years of age with any of the following conditions: chronic heart disease (particularly cyanotic congenital heart disease and cardiac failure); chronic lung disease (including asthma if treated with high-dose oral corticosteroid therapy); diabetes mellitus; cerebrospinal fluid leak; cochlear implant; sickle cell disease and other hemoglobinopathies; anatomic or functional asplenia; HIV infection; chronic renal failure; nephrotic syndrome; diseases associated with treatment with immunosuppressive drugs or radiation therapy, including malignant neoplasms, leukemias, lymphomas, and Hodgkin's disease; solid organ transplantation; or congenital immunodeficiency:
 1. Administer 1 dose of PCV13 if any incomplete schedule of 3 doses of PCV (PCV7 and/or PCV13) were received previously.
 2. Administer 2 doses of PCV13 at least 8 weeks apart if unvaccinated or any incomplete schedule of fewer than 3 doses of PCV (PCV7 and/or PCV13) were received previously.
 3. Administer 1 supplemental dose of PCV13 if 4 doses of PCV7 or other age-appropriate complete PCV7 series was received previously.
 4. The minimum interval between doses of PCV (PCV7 or PCV13) is 8 weeks.
 5. For children with no history of PPSV23 vaccination, administer PPSV23 at least 8 weeks after the most recent dose of PCV13.

6. Pneumococcal vaccines (cont'd)

- For children aged 6 through 18 years who have cerebrospinal fluid leak; cochlear implant; sickle cell disease and other hemoglobinopathies; anatomic or functional asplenia; congenital or acquired immunodeficiencies; HIV infection; chronic renal failure; nephrotic syndrome; diseases associated with treatment with immunosuppressive drugs or radiation therapy, including malignant neoplasms, leukemias, lymphomas, and Hodgkin's disease; generalized malignancy; solid organ transplantation; or multiple myeloma:
 1. If neither PCV13 nor PPSV23 has been received previously, administer 1 dose of PCV13 now and 1 dose of PPSV23 at least 8 weeks later.
 2. If PCV13 has been received previously but PPSV23 has not, administer 1 dose of PPSV23 at least 8 weeks after the most recent dose of PCV13.
 3. If PPSV23 has been received but PCV13 has not, administer 1 dose of PCV13 at least 8 weeks after the most recent dose of PPSV23.
- For children aged 6 through 18 years with chronic heart disease (particularly cyanotic congenital heart disease and cardiac failure), chronic lung disease (including asthma if treated with high-dose oral corticosteroid therapy), diabetes mellitus, alcoholism, or chronic liver disease, who have not received PPSV23, administer 1 dose of PPSV23. If PCV13 has been received previously, then PPSV23 should be administered at least 8 weeks after any prior PCV13 dose.
- A single revaccination with PPSV23 should be administered 5 years after the first dose to children with sickle cell disease or other hemoglobinopathies; anatomic or functional asplenia; congenital or acquired immunodeficiencies; HIV infection; chronic renal failure; nephrotic syndrome; diseases associated with treatment with immunosuppressive drugs or radiation therapy, including malignant neoplasms, leukemias, lymphomas, and Hodgkin's disease; generalized malignancy; solid organ transplantation; or multiple myeloma.

7. Inactivated poliovirus vaccine (IPV). (Minimum age: 6 weeks)

Routine vaccination:

- Administer a 4-dose series of IPV at ages 2, 4, 6 through 18 months, and 4 through 6 years. The final dose in the series should be administered on or after the fourth birthday and at least 6 months after the previous dose.

Catch-up vaccination:

- In the first 6 months of life, minimum age and minimum intervals are only recommended if the person is at risk of imminent exposure to circulating poliovirus (i.e., travel to a polio-endemic region or during an outbreak).
- If 4 or more doses are administered before age 4 years, an additional dose should be administered at age 4 through 6 years and at least 6 months after the previous dose.
- A fourth dose is not necessary if the third dose was administered at age 4 years or older and at least 6 months after the previous dose.
- If both OPV and IPV were administered as part of a series, a total of 4 doses should be administered.
- Regardless of the child's current age, IPV is not routinely recommended for U.S. residents aged 18 years or older.
- For other catch-up guidance, see Figure 2.

8. Influenza vaccines. (Minimum age: 6 months for inactivated influenza vaccine [IIV], 2 years for live, attenuated influenza vaccine [LAIV])

Routine vaccination:

- Administer influenza vaccine annually to all children beginning at age 6 months. For most healthy, nonpregnant persons aged 2 through 49 years, either LAIV or IIV may be used. However, LAIV should NOT be administered to some persons, including 1) persons who have experienced severe allergic reactions to LAIV, any of its components, or to a previous dose of any other influenza vaccine; 2) children 2 through 17 years receiving aspirin or aspirin-containing products; 3) persons who are allergic to eggs; 4) pregnant women; 5) immunosuppressed persons; 6) children 2 through 4 years of age with asthma or who had wheezing in the past 12 months; or 7) persons who have taken influenza antiviral medications in the previous 48 hours. For all other contraindications and precautions to use of LAIV, see *MMWR* August 15, 2014 / 63(32);691-697 [40 pages] available at <http://www.cdc.gov/mmwr/pdf/wk/mm6332.pdf>.

For children aged 6 months through 8 years:

- For the 2014-15 season, administer 2 doses (separated by at least 4 weeks) to children who are receiving influenza vaccine for the first time. Some children in this age group who have been vaccinated previously will also need 2 doses. For additional guidance, follow dosing guidelines in the 2014-15 ACIP influenza vaccine recommendations, *MMWR* August 15, 2014 / 63(32);691-697 [40 pages] available at <http://www.cdc.gov/mmwr/pdf/wk/mm6332.pdf>.
- For the 2015-16 season, follow dosing guidelines in the 2015 ACIP influenza vaccine recommendations.

For persons aged 9 years and older:

- Administer 1 dose.

For further guidance on the use of the vaccines mentioned below, see: <http://www.cdc.gov/vaccines/hcp/acip-recs/index.html>.

9. Measles, mumps, and rubella (MMR) vaccine. (Minimum age: 12 months for routine vaccination)

Routine vaccination:

- Administer a 2-dose series of MMR vaccine at ages 12 through 15 months and 4 through 6 years. The second dose may be administered before age 4 years, provided at least 4 weeks have elapsed since the first dose.
- Administer 1 dose of MMR vaccine to infants aged 6 through 11 months before departure from the United States for international travel. These children should be revaccinated with 2 doses of MMR vaccine, the first at age 12 through 15 months (12 months if the child remains in an area where disease risk is high), and the second dose at least 4 weeks later.
- Administer 2 doses of MMR vaccine to children aged 12 months and older before departure from the United States for international travel. The first dose should be administered on or after age 12 months and the second dose at least 4 weeks later.

Catch-up vaccination:

- Ensure that all school-aged children and adolescents have had 2 doses of MMR vaccine; the minimum interval between the 2 doses is 4 weeks.

10. Varicella (VAR) vaccine. (Minimum age: 12 months)

Routine vaccination:

- Administer a 2-dose series of VAR vaccine at ages 12 through 15 months and 4 through 6 years. The second dose may be administered before age 4 years, provided at least 3 months have elapsed since the first dose. If the second dose was administered at least 4 weeks after the first dose, it can be accepted as valid.

Catch-up vaccination:

- Ensure that all persons aged 7 through 18 years without evidence of immunity (see *MMWR* 2007 / 56 [No. RR-4], available at <http://www.cdc.gov/mmwr/pdf/rr/rr5604.pdf>) have 2 doses of varicella vaccine. For children aged 7 through 12 years, the recommended minimum interval between doses is 3 months (if the second dose was administered at least 4 weeks after the first dose, it can be accepted as valid); for persons aged 13 years and older, the minimum interval between doses is 4 weeks.

11. Hepatitis A (HepA) vaccine. (Minimum age: 12 months)

Routine vaccination:

- Initiate the 2-dose HepA vaccine series at 12 through 23 months; separate the 2 doses by 6 to 18 months.
- Children who have received 1 dose of HepA vaccine before age 24 months should receive a second dose 6 to 18 months after the first dose.
- For any person aged 2 years and older who has not already received the HepA vaccine series, 2 doses of HepA vaccine separated by 6 to 18 months may be administered if immunity against hepatitis A virus infection is desired.

Catch-up vaccination:

- The minimum interval between the two doses is 6 months.

Special populations:

- Administer 2 doses of HepA vaccine at least 6 months apart to previously unvaccinated persons who live in areas where vaccination programs target older children, or who are at increased risk for infection. This includes persons traveling to or working in countries that have high or intermediate endemicity of infection; men having sex with men; users of injection and non-injection illicit drugs; persons who work with HAV-infected primates or with HAV in a research laboratory; persons with clotting-factor disorders; persons with chronic liver disease; and persons who anticipate close personal contact (e.g., household or regular babysitting) with an international adoptee during the first 60 days after arrival in the United States from a country with high or intermediate endemicity. The first dose should be administered as soon as the adoption is planned, ideally 2 or more weeks before the arrival of the adoptee.

12. Human papillomavirus (HPV) vaccines. (Minimum age: 9 years for HPV2 [Cervarix] and HPV4 [Gardasil])

Routine vaccination:

- Administer a 3-dose series of HPV vaccine on a schedule of 0, 1-2, and 6 months to all adolescents aged 11 through 12 years. Either HPV4 or HPV2 may be used for females, and only HPV4 may be used for males.
- The vaccine series may be started at age 9 years.
- Administer the second dose 1 to 2 months after the first dose (minimum interval of 4 weeks); administer the third dose 24 weeks after the first dose and 16 weeks after the second dose (minimum interval of 12 weeks).

Catch-up vaccination:

- Administer the vaccine series to females (either HPV2 or HPV4) and males (HPV4) at age 13 through 18 years if not previously vaccinated.
- Use recommended routine dosing intervals (see Routine vaccination above) for vaccine series catch-up.

13. Meningococcal conjugate vaccines. (Minimum age: 6 weeks for Hib-MenCY [MenHibrix], 9 months for MenACWY-D [Menactra], 2 months for MenACWY-CRM [Menveo])

Routine vaccination:

- Administer a single dose of Menactra or Menveo vaccine at age 11 through 12 years, with a booster dose at age 16 years.
- Adolescents aged 11 through 18 years with human immunodeficiency virus (HIV) infection should receive a 2-dose primary series of Menactra or Menveo with at least 8 weeks between doses.
- For children aged 2 months through 18 years with high-risk conditions, see below.

Catch-up vaccination:

- Administer Menactra or Menveo vaccine at age 13 through 18 years if not previously vaccinated.
- If the first dose is administered at age 13 through 15 years, a booster dose should be administered at age 16 through 18 years with a minimum interval of at least 8 weeks between doses.
- If the first dose is administered at age 16 years or older, a booster dose is not needed.
- For other catch-up guidance, see Figure 2.

Vaccination of persons with high-risk conditions and other persons at increased risk of disease:

- Children with anatomic or functional asplenia (including sickle cell disease):
 1. Menveo
 - o *Children who initiate vaccination at 8 weeks through 6 months:* Administer doses at 2, 4, 6, and 12 months of age.
 - o *Unvaccinated children 7 through 23 months:* Administer 2 doses, with the second dose at least 12 weeks after the first dose AND after the first birthday.
 - o *Children 24 months and older who have not received a complete series:* Administer 2 primary doses at least 8 weeks apart.
 2. MenHibrix
 - o *Children 6 weeks through 18 months:* Administer doses at 2, 4, 6, and 12 through 15 months of age.
 - o If the first dose of MenHibrix is given at or after 12 months of age, a total of 2 doses should be given at least 8 weeks apart to ensure protection against serogroups C and Y meningococcal disease.
 3. Menactra
 - o *Children 24 months and older who have not received a complete series:* Administer 2 primary doses at least 8 weeks apart. If Menactra is administered to a child with asplenia (including sickle cell disease), do not administer Menactra until 2 years of age and at least 4 weeks after the completion of all PCV13 doses.
- Children with persistent complement component deficiency:
 1. Menveo
 - o *Children who initiate vaccination at 8 weeks through 6 months:* Administer doses at 2, 4, 6, and 12 months of age.
 - o *Unvaccinated children 7 through 23 months:* Administer 2 doses, with the second dose at least 12 weeks after the first dose AND after the first birthday.
 - o *Children 24 months and older who have not received a complete series:* Administer 2 primary doses at least 8 weeks apart.
 2. MenHibrix
 - o *Children 6 weeks through 18 months:* Administer doses at 2, 4, 6, and 12 through 15 months of age.
 - o If the first dose of MenHibrix is given at or after 12 months of age, a total of 2 doses should be given at least 8 weeks apart to ensure protection against serogroups C and Y meningococcal disease.
 3. Menactra
 - o *Children 9 through 23 months:* Administer 2 primary doses at least 12 weeks apart.
 - o *Children 24 months and older who have not received a complete series:* Administer 2 primary doses at least 8 weeks apart.
- For children who travel to or reside in countries in which meningococcal disease is hyperendemic or epidemic, including countries in the African meningitis belt or the Hajj, administer an age-appropriate formulation and series of Menactra or Menveo for protection against serogroups A and W meningococcal disease. Prior receipt of MenHibrix is not sufficient for children traveling to the meningitis belt or the Hajj because it does not contain serogroups A or W.
- For children at risk during a community outbreak attributable to a vaccine serogroup, administer or complete an age- and formulation-appropriate series of MenHibrix, Menactra, or Menveo.
- For booster doses among persons with high-risk conditions, refer to *MMWR* 2013 / 62(RR02);1-22, available at <http://www.cdc.gov/mmwr/preview/mmwrhtml/rr6202a1.htm>.

For other catch-up recommendations for these persons, and complete information on use of meningococcal vaccines, including guidance related to vaccination of persons at increased risk of infection, see *MMWR* March 22, 2013 / 62(RR02);1-22, available at <http://www.cdc.gov/mmwr/pdf/rr/rr6202.pdf>.

FREE

Ice hockey is an increasingly popular sport that allows intentional collision in the form of body checking for males but not for females. There is a two- to threefold increased risk of all injury, severe injury, and concussion related to body checking at all levels of boys' youth ice hockey. The American Academy of Pediatrics reinforces the importance of stringent enforcement of rules to protect player safety as well as educational interventions to decrease unsafe tactics. To promote ice hockey as a lifelong recreational pursuit for boys, the American Academy of Pediatrics recommends the expansion of nonchecking programs and the restriction of body checking to elite levels of boys' youth ice hockey, starting no earlier than 15 years of age. *Pediatrics* 2014;133:1151–1157

INTRODUCTION

Ice hockey is a high-speed sport enjoyed by increasing numbers of children and adolescents in an expanding geographic distribution of the United States. It can subsequently become a lifelong recreational activity, enjoyed by many adults well into their senior years. According to USA Hockey (the national governing body for amateur ice hockey in the United States), there were more than 350 000 youth (305 000 boys, 50 000 girls) younger than 19 years participating in hockey programs in 2011–2012, increased from approximately 200 000 in 2000, when the American Academy of Pediatrics (AAP) published “Safety in Youth Ice Hockey: The Effects of Body Checking.”^{1,2} Like football, rugby, and wrestling, boys' ice hockey is categorized as a collision sport in that intentional physical contact may be used as a strategic technique. A body “check” is defined as a defensive player's intentional tactic to separate the puck carrier from the puck—not to injure or intimidate the opposing player—with a distinct and definable moment of impact (“hit”). In contrast, body “contact” is also a defensive tactic in which the athlete's body is used to legally block or impede the progress of the puck carrier, without delivering a hit to separate the carrier from the puck. Unlike other collision sports, hockey is played on a hard surface, contained by unyielding walls (“boards”) and acrylic windows (“glass”). Previous safety interventions focused on protective equipment and enforcement of rules have largely eliminated dental, eye, and facial injuries in youth hockey and greatly decreased cervical spine injuries. However, because of ongoing concerns that a high

number and proportion of boys' ice hockey injuries are attributable to body checking, the AAP has elected to reassess its 2000 recommendation that "body checking should not be allowed in youth hockey for children age 15 years or younger." Because body checking is not allowed at any level of girls' or women's ice hockey, this statement focuses on boys' youth ice hockey.

INJURY EPIDEMIOLOGY

Every year in the United States, an estimated 12 590 players younger than 19 years seek care in the emergency department for ice hockey–related injuries³; the yearly estimated incidence of ice hockey–related injuries among 9- to 14-year-olds increased by 163% from 1990 to 2006.⁴ For the years 2008–2012, the total injury rate for boys' high school ice hockey in the United States ranged from 2.03 to 2.56 injuries per 1000 athlete-exposures (AEs, ie, 1 athlete participating in 1 practice or competition), with a game-related injury rate of 4.18 to 6.08 per 1000 AEs, second only to boys' high school football (total injury rate, 3.61–4.02 per 1000 AE; game-related injury rate, 11.28–12.72).^{5–8} For this same time period, the proportion of severe injuries (>21 days' time loss) sustained during competition in boys' ice hockey (6%–17%) was comparable to that in football (6%–12%). A companion AAP

policy statement on tackling in youth football is in development.

Risk of Injury From Body Checking

Youth ice hockey leagues are typically stratified by age (Table 1) and competition level, as determined by talent, which is often associated with increasing training time, volume, and intensity as well as more extensive travel to games and tournaments. Because there have been several rule changes in boys' youth ice hockey over the past decade, the association between body checking and injury has become a focus of rigorous scientific examination (Table 2). Several investigators have examined cross-sectional data from the Canadian Hospitals Injury Reporting and Prevention Program (CHIRPP) injury surveillance system. A 2006 analysis of data on 4736 hockey injuries from CHIRPP between 1995 and 2002 found that the majority of the injuries in younger divisions (10–13 years of age) occurred in Ontario, where body checking was allowed at those ages, and nearly half of those injuries were related to checking.⁹ Another analysis of CHIRPP data from 1994 through 2004 on 8552 hockey-related injuries (52.2% attributable to body checking), after a rule change in 1998 that lowered the age for body checking (from 12–13 years to 10–11 years of age), showed that the odds of a body-checking-related injury increased twofold in

the newly allowed checking divisions.¹⁰ In contrast, a retrospective analysis of data from 1997 through 2007 found that the number of body-checking-related injuries for which players were treated in 2 Ontario emergency departments did not change significantly after a rule change in 2002 that lowered the age at which body checking was introduced from 12 to 13 years to 9 to 10 years of age.¹¹ Research examining the same 2002 rule change in a data set from Alberta similarly noted no increase in visits to emergency departments for body-checking-related injuries in that province.¹² However, the majority of other cohorts studied have demonstrated increased risk of injury with body checking.

In a 5-year study of youth ice hockey players 4 to 18 years of age, injuries from unintentional collisions were more common than were injuries from intentional contact,¹³ but the injury rates for both intentional and unintentional collisions were over 3 times higher (and the overall risk of injury nearly 4 times higher) in divisions that allowed body checking.¹⁴ A 2006 Canadian study of 986 youth ice hockey players 9 to 16 years of age estimated that 45% of all injuries occurred as a result of body checking.¹⁵ Comparisons within the same youth ice hockey programs have demonstrated that older age groups that allowed body checking sustained 3 to 5 times higher injury rates than the youngest age group, which did not allow checking.¹⁵ A large prospective study comparing 2 cohorts of 11- and 12-year-olds (Pee Wee) in Canadian provinces with (Alberta) and without (Quebec) body checking demonstrated that the rate of injury was more than 3 times higher in Alberta, including severe injury defined as time loss more than 1 week (injury rate ratio [IRR], 3.30; 95% confidence interval

TABLE 1 Current Age Jurisdictions in Youth Ice Hockey in North America^a

Category	Age (y) on December 31 of the Playing Season	Where Body Checking Is Allowed in 2013–2014 Season
Initiation (in Canada)	<7	Nowhere
Mite (US), Novice (Canada)	7 and 8	Nowhere
Squirt (US), Atom (Canada)	9 and 10	Nowhere
Pee Wee	11 and 12	Nowhere ^{b,c}
Bantam	13 and 14	US, Canada
Midget	15–17	US, Canada

^a Age categories were shifted down by 1 y in Canada in 2002.

^b In the United States, age of legal body checking in games raised from Pee Wee to Bantam starting with 2011–2012 season.

^c In Canada, age of legal body checking in games raised from Pee Wee to Bantam starting with 2013–2014 season.

TABLE 2 Estimated Risk of All Injury and Concussion From Body Checking

Study	Estimate of Risk of Body Checking (All Injury)	Estimate of Risk of Body Checking (Concussion)
Hagel, 2006 ⁴⁷	Rate ratio 1.9 (CI 1.4–2.4)	Rate ratio 3.4 (CI 1.4–8.4)
Emery, 2006 ¹⁵	Pee Wee, RR 2.97 (CI 1.63–5.8) Bantam RR 3.72 (CI 2.08–7.14) Midget RR 5.43 (CI 3.14–10.17)	Pee Wee RR 3.4 (0.93–18.61) Bantam RR 4.04 (1.17–21.54) Midget RR 3.41 (1.02–17.87)

Cusimano, 2011 ¹⁰	OR 2.20 (CI 1.70–2.84)	OR 10.08 (2.35–43.29)
Darling, 2011 ¹³	Rate ratio 3.75 (CI 1.51–9.34)	

RR, relative risk.

[CI], 1.77–6.17).¹⁶ Two systematic reviews of the literature published in 2009 (20 studies) and 2010 (10 studies) have examined the association between body checking and injury in boys' ice hockey. All but 1 of their included studies demonstrated that body checking increases the risk of all injuries, with the meta-analysis of 5 studies performed by Emery et al reporting a combined IRR of 2.45 (95% CI, 1.7–3.6).^{17,18}

Specific Risk of Concussion

As noted in the 2010 AAP clinical report "Sport-Related Concussion in Children and Adolescents," concussion is an increasingly recognized concern in many youth sports in the United States, including ice hockey.¹⁹ A recent study of high school sports revealed that the concussion rate in boys' ice hockey (5.4 per 10 000 AEs) was second only to football (6.4 per 10 000 AEs); however, concussions accounted for a greater proportion of total injuries in boys' ice hockey (22.2%) than any of the other 20 sports, with 30% of the concussions in ice hockey resulting from a player being body checked.²⁰ Other estimates of the proportion of concussions resulting from being checked and/or delivering the check are as high as 30% to 70%.^{5–8} Concussion was reported as the most common specific injury type in Canadian minor boys' ice hockey, with a higher risk of concussion in age

groups that allowed legal body checking.¹⁵ Studies demonstrating an increased risk of injury related to body checking also demonstrated increased risk of concussion (Table 2). The meta-analysis by Emery et al of 4 studies estimated a combined odds ratio (OR) of 1.71 (95% CI 1.2–2.44) for body checking as a risk factor for concussion,¹⁷ whereas the prospective cohort study by Emery et al comparing Canadian provinces that allowed body checking in Pee Wee (11 and 12 years of age) boys' hockey found an IRR of 3.61 (95% CI 1.16–11.23) for severe concussion (more than 10 days lost from sport).¹⁶

Recent research has suggested that body collisions may have adverse effects without causing frank concussion. Studies using in-helmet accelerometers showed that exposure to repetitive head impact sustained by collegiate football and ice hockey players was associated with significant declines on neuropsychological cognitive testing compared with non-collision collegiate sports athletes over 1 playing season, independent of concussion diagnosis.²¹ Using similar technology, female intercollegiate ice hockey players, who are not allowed to check, sustained less frequent and lower magnitude head impacts than their male counterparts.²² This nascent area of investigation raises the concern that even early recognition and proper management of concussion—

a form of tertiary injury prevention—may be inadequate protection for the central nervous system.

Risks of "Aggressive Playing Style"

Body checking is associated with a more aggressive style of play, and aggressive play is associated with more severe injury. Players in leagues in which body checking is allowed have been shown to have lower levels of empathy, to have higher levels of aggression, and to respond more positively to statements about injuring another player with a body check to increase their team's chances of winning as well as body checking an opposing player even if they knew it would injure the other player.²³ A study examining rule infractions from 55 games at the Bantam level in 2 Canadian provinces revealed that illegal collisions or infractions, categorized as boarding, charging, checking from behind, elbowing, and intentional head contact, resulted in higher linear head accelerations and more severe head impacts than legal collisions.²⁴ More frequent and higher-intensity physical contact occurs in leagues that allow body checking.²⁵ An aggressive style of play (such as lunging or launching at the opponent) to ensure physical contact with disregard for the location of the puck has been observed in players at the Bantam level.²⁶ These data suggest that delaying body checking until later ages may also reduce aggressive play overall, which could lead to an even greater reduction in injury rates.

RISK OF AGE, SIZE, OR MATURITY DISCREPANCY

The 2000 AAP statement expressed concern that large discrepancies in relative age, size, and maturity may lead to an increased injury rate in those who are younger, smaller, and less physically developed. Most studies

that have examined age as a risk factor have found that older relative age, not younger, is associated with a higher rate of injury, particularly at higher levels of competition.^{27,28} It has been suggested that in these analyses, age was a proxy for magnitude or intensity of exposure. In 2 studies that examined differences in injury proportions in players in their first and second constituent years within age categories, injured players were more likely to be in constituent year 2 in the Atom (7 and 8 years of age) and Pee Wee (11 and 12 years of age) divisions and in the highest level of competition.^{16,29} In contrast, Bantam (13 and 14 years of age) players in their first year have been determined to have an increased risk of injury.²⁷ This is likely because the Bantam level contains the broadest range of physical maturity and body size.

Although the few studies that have examined the association between injury risk and physical maturity, as determined by Tanner staging, bone age, or other noninvasive measures, also have suggested that more advanced players sustain more injuries, there is no research examining the risk of injury attributable to athletes of discrepant maturity status directly competing and potentially colliding.^{30,31} Nonetheless, the range of physical development represented in the 13- and 14-year-old Bantam age category, which spans the typical male peak height velocity at 13.5 years of age, is wide enough to cause concern, with the height and weight of male Bantam players reported to differ by as much as 41 cm and 48 kg, respectively.³² An anthropomorphic study of youth football players in Michigan demonstrated a mean weight of 38.6 kg and BMI of 17.5 kg/m² in 13-year-olds categorized as “late maturing,” and “early maturing” 14-year-olds had corresponding means of 77.3 kg weight and 26.6 kg/m²

BMI.³³ Pop Warner Youth Football addresses this issue by restricting players above certain size thresholds to specified positions on the field (offensive and defensive line) where high-speed collisions are less likely. In a single study, smaller Pee Wee (11 and 12 years of age, ≤ 37 kg) but not Bantam (13 and 14 years of age, ≤ 52 kg) youth hockey players have been determined to be at increased risk of injury, but the authors’ chosen 25th percentile weight cut points may not have had adequate sensitivity.^{16,27}

SAFETY STRATEGIES IN YOUTH ICE HOCKEY

Protective Equipment

Ice hockey players wear head-to-toe protective equipment. Although studies proving the merit of most of the gear is lacking, the speed of the puck and the use of curved sticks support its continued use. The piece of equipment that has generated the greatest controversy has been the helmet and facemask. Although some manufacturers have claimed protection from concussion for their particular models, no helmets have demonstrated evidence of such effect. Nonetheless, it is worth reinforcing that investigators have consistently found the overall injury rate to be significantly lower in players with helmets and full-face shield protection.^{34–40}

Rule Changes and Enforcement

The Canadian Ice Hockey Spinal Registry identified mechanisms of catastrophic cervical spine injury in the 1980s.⁴¹ Decreases in the incidence of these injuries followed more stringent enforcement of rules to prevent checking from behind, particularly near or into the boards, in addition to educational interventions. For the

2012–2013 season, the National Federation of State High School Associations approved rule changes to further strengthen enforcement aimed at eliminating dangerous play in hockey games. Hitting an opponent from behind into the boards or the goal frame is now considered a flagrant violation resulting in a game disqualification. The 2010 Ice Hockey Summit on Concussion called for a zero-tolerance policy with regard to any contact to the head, whether intentional or incidental.⁴² Nevertheless, Emery and Meeuwisse reported in 2006 that 97% of body-checking-related injuries were sustained by a player receiving a check, but only 15% of these injuries resulted in a penalty.¹⁵

Coaching and Education

Programs in both the United States and Canada that have emphasized coach and player education to teach youth to keep their heads up, especially when they are about to receive a check, and to respect their opponents by not checking them from behind have also coincided with a decrease in the incidence of cervical spine injury. ThinkFirst Canada’s SMART HOCKEY initiative and USA Hockey’s Heads Up Hockey curriculum aim to apply similar techniques to concussion recognition and prevention, but the effectiveness of these programs has yet to be assessed. USA Hockey’s American Development Model emphasizes skill and skating development free from fear of being body checked at younger ages, while implementing a progressive curriculum to teach proper body control, angling, and body contact, reserving body-checking skills until the 11- to 12-year-old age group.

Minnesota’s Hockey Education Program was implemented in 2004 to provide safer and more enjoyable

participation through Fair Play, a program first introduced 2 decades ago, that rewards teams with good sportsmanship specifically by allowing them to earn additional points for receiving fewer penalties.⁴³ In a 1999 study, the injury rate was 5 times higher in games played without the Fair Play rules in a tournament of Minnesota high school–age community-based teams.⁴⁴ Unfortunately, a 2005 study evaluating the effectiveness of the fair play concept in Quebec reported no significant difference in the injury rate, with either delivering or receiving a body check the primary cause for almost half of the injuries.⁴⁵ Several other interventions to promote safer play in youth ice hockey implemented both before and since the 2000 AAP statement similarly lack evidence for effectiveness in reducing injury rates.⁴⁶

No Protective Effect of Earlier Introduction of Body Checking

Proponents of body checking suggest that earlier introduction of body checking will increase skill and decrease injury related to body checking in older age groups, but there is limited evidence to support this potential effect. Older players (14–15 years of age) from a Canadian province that allowed checking at a younger age demonstrated an increased odds of a checking-related injury (OR, 1.90; 95% CI, 1.36–2.66) compared with their peers in a province allowing checking for the first time.⁹ After a lowering of age classifications by Hockey Canada in 2002, injury rates among 10-year-old Squirts (body checking never allowed) and 12-year-old Pee Wees (body checking always allowed) in Alberta did not change, but 11-year-old Pee Wee players newly allowed to body check sustained a significantly higher number of injuries.⁴⁷ A

subsequent prospective cohort study of almost 2000 male players 13 to 14 years of age, comparing injury rates in those with 2 years of body-checking experience with those being introduced to body checking for the first time, demonstrated that the game-related overall rates of injury, concussion, and concussion with more than 10 days of time loss were not significantly lower in players with 2 years of body-checking experience.²⁷ The injury rate associated with body checking was higher than other mechanisms of injury, and the rate of injury from body checking was not significantly lower in the group with body-checking experience (IRR, 0.82; 95% CI, 0.59–1.15), although the risk of injury resulting in greater than 1 week of time loss from sport was 33% lower among players with 2 years of body-checking experience.

OFFICIAL POLICY OF MEDICAL ASSOCIATIONS REGARDING HOCKEY SAFETY

Since the 2000 AAP statement, the American Osteopathic Academy of Sports Medicine (2002), the Canadian Academy of Sports Medicine (2007), and the Canadian Pediatric Society (2012) have released position statements about injuries in youth ice hockey. USA Hockey raised the age of legal body checking in games from Pee Wee (11 and 12 years of age) to Bantam (13 and 14 years of age) for the 2011–2012 season subsequent to the 2010 Ice Hockey Summit, which called for postponing legal body checking in youth games until 13 years of age. State and local youth hockey associations can offer leagues without body checking—often called “recreational”—at all ages, but competition with high school and other elite hockey programs that may promise the potential for advancement to higher levels of ice

hockey, which typically sanction body checking, may make this option rare in many communities.

CONCLUSIONS

There is consistent evidence that body checking remains a significant risk factor for injury at all levels of boys' youth ice hockey. Concussion is a particularly concerning problem and is often the result of body-checking activity. Body checking can also be associated with more aggressive play that further increases the risk of serious injury. The delay of body checking to higher ages has been shown to decrease risk of injury in 11- and 12-year-olds. Although data for older boys is less extensive, it is reasonable to conclude that removing body checking would reduce injury rates and severity at all ages, particularly benefitting 13- and 14-year-olds, who may be more vulnerable because of wide discrepancies in physical maturity.

RECOMMENDATIONS

In the continued interest of promoting boys' youth ice hockey as a safe, life-long recreational pursuit, the AAP recommends:

1. Expansion of nonchecking programs for boys aged 15 years and older. Pediatricians should advocate for development of these programs in their communities and encourage their patients to participate in them.
2. Restriction of body checking in boys' ice hockey games to the highest competition levels (eg, AAA, AA, Tier I, Tier II), starting no earlier than 15 years of age. Body-checking skills could be taught in practices starting at 13 years of age for those players geared to elite participation.

3. Strict enforcement of zero-tolerance rules against any contact to the head, whether incidental or intentional.
4. Reinforcement of rules to prevent body contact from behind, particularly into or near the boards.
5. Continued emphasis on coaching and education to prevent body contact from behind.
6. More research into the effects of legal body checking, including specific attention to injury risk attributable to differences in size and physical maturity.

Referral to Pediatric Surgical Specialists

.....

- *Policy Statement*

POLICY STATEMENT

Referral to Pediatric Surgical Specialists

abstract

FREE

The American Academy of Pediatrics, with the collaboration of the Surgical Sections of the American Academy of Pediatrics, has created referral recommendations intended to serve as voluntary practice parameters to assist general pediatricians in determining when and to whom to refer their patients for pediatric surgical specialty care. It is recognized that these recommendations may be difficult to implement, because communities vary in terms of access to major pediatric medical centers. Limited access does not negate the value of the recommendations, however, because the child who needs specialized surgical and anesthetic care is best served by the skills of the appropriate pediatric surgical team. Major congenital anomalies, malignancies, major trauma, and chronic illnesses (including those associated with preterm birth) in infants and children should be managed by pediatric medical subspecialists and pediatric surgical specialists at pediatric referral centers that can provide expertise in many areas, including the pediatric medical subspecialties and surgical specialties of pediatric radiology, pediatric anesthesiology, pediatric pathology, and pediatric intensive care. The optimal management of the child with complex problems, chronic illness, or disabilities requires coordination, communication, and cooperation of the pediatric surgical specialist with the child's primary care pediatrician or physician. *Pediatrics* 2014;133:350–356

When a surgical condition has been identified in a child, ideally a pediatric surgical specialist should be called to address the issues related to this condition with the family and the respective pediatrician. It is recognized that communities differ in their medical resources. Specialists of all varieties tend to concentrate in areas of higher population density. In communities where it would be a hardship to the family and the child to travel long distances, the family, in conjunction with the primary care pediatrician/physician, should weigh the advantages of traveling to a center with a pediatric surgical specialist for surgical care. The primary care pediatrician or physician should consider calling the pediatric surgical specialist to discuss whether a consultation is advised in cases in which, geographically, the specialist is not near.

Finally, however, it should be noted that these recommendations are voluntary for practice management. Each pediatrician must make an independent judgment in each case on the basis of facts and circumstances presented to him or her. Whereas in some areas evidence

is available for better outcomes with specialist assessment and treatment, these recommendations are, in large part, derived from expert opinion of children's surgical specialists.

REFERRAL TO A CONGENITAL HEART SURGEON

Care of neonates, infants, children, and teenagers with congenital heart disease should occur at specialized centers that include the following: congenital heart surgeons, pediatric cardiologists subspecializing in invasive and noninvasive cardiology, pediatric cardiac anesthesiologists, and pediatric cardiac critical care specialists. Congenital heart surgeons operate on the heart and great vessels of neonates, infants, children, teenagers, and adults with congenital heart disease. A congenital heart surgeon has completed training in general surgery and thoracic surgery, is certified by the American Board of Thoracic Surgery, and has further specialized in the surgical treatment of congenital heart disease. The American Board of Thoracic Surgery now offers a subspecialty certificate in congenital heart surgery that can be earned by those Diplomates of the American Board of Thoracic Surgery who have specialized in congenital heart surgery, including surgeons presently in the practice of congenital heart surgery and those completing approved training programs. This certificate recognizes training and experience in the care of individuals with congenital heart disease of all ages. Congenital heart surgeons should care for the following groups of patients:

- all neonates, infants, children, and teenagers with congenital heart disease requiring heart surgery;
- adults with complex congenital heart disease requiring heart surgery;

- all neonates, infants, children, and teenagers with acquired heart disease requiring cardiac surgery (eg, endocarditis, cardiac tumors, Kawasaki disease); and
- all neonates, infants, children, and teenagers with end-stage heart disease requiring transplantation or mechanical support, whether attributable to congenital heart disease or myopathies.

REFERRAL TO A PEDIATRIC DENTIST

A pediatric dentist has completed 4 years of dental school and a 2- to 3-year postgraduate residency in pediatric dentistry. The American Board of Pediatric Dentistry offers a subspecialty certificate in pediatric dentistry that can be earned by those Diplomates of the American Board of Dentistry who have specialized in pediatric dentistry by completing approved training programs. This certificate recognizes training and experience in the provision of oral health care in children. Postgraduate training for a pediatric dentist includes training in infant and early child oral disease risk assessment; anticipatory guidance; hospital dentistry; oral sedation; general anesthesia; infant oral health care; behavior guidance; specialized care for the primary, mixed, and adult dentitions; pediatric oral pathology; prevention; and interventional orthodontics. For purposes of developing these recommendations, the following age group definitions are used: infant (0–1 year), child (2–12 years), and adolescent (13–18 years). All children should have a Dental Home within 6 months of the eruption of the first tooth.

A pediatric patient who presents with any of the following conditions should be referred for prompt consultation to a pediatric dentist or a general dentist who maintains

a high level of competence in the care of children:

- an infant determined to have high caries risk through a caries risk assessment;
- an infant/child/adolescent with a severe developmental disability that makes management of behavior and clinical care challenging;
- an infant/child/adolescent with rampant or extensive dental caries requiring oral sedation or general anesthesia for treatment;
- an infant/child/adolescent preparing to undergo radiation therapy, chemotherapy, and/or hematopoietic stem cell transplantation;
- an infant/child/adolescent who is medically compromised and whose medical condition would deteriorate without appropriate dental treatment;
- an infant/child/adolescent with a facial swelling of unknown origin;
- a child with oral habits (ie, thumb sucking, pacifier, tongue thrust) that may require intervention to prevent or improve a dental malocclusion;
- an infant/child/adolescent with a possible oral abnormality;
- a child/adolescent for the management of prematurely loose teeth and/or periodontal disease;
- an infant/child/adolescent with a cleft lip/palate or other craniofacial anomaly;
- a child/adolescent who is intending to participate in contact athletic activities that require fabrication of an athletic mouth guard;
- an infant/child/adolescent with suspected dental neglect or abuse;
- an infant/child/adolescent who suffers dental trauma (ie, tooth fracture, intrusion, luxation, and avulsion); or

- an infant, child and/or adolescent whose caregiver requests the care of a pediatric dental specialist.

Referral of a patient to a pediatric dentist may result in referrals to other dental specialists (orthodontist, oral surgeon, endodontist, periodontist, etc) for appropriate care, with the pediatric dentist managing the care and referral of the patient.

REFERRAL TO A PEDIATRIC NEUROLOGIC SURGEON

A pediatric neurosurgeon is identified by board certification. The American Board of Pediatric Neurologic Surgery offers a subspecialty certificate in pediatric neurologic surgery that can be earned by those Diplomates of the American Board of Neurologic Surgery who have specialized in pediatric neurologic surgery by completing approved training programs. This certificate recognizes training and experience in the care of children with neurologic surgical problems, as well as the care of congenital disorders throughout the life span, as demonstrated by a minimum of a 75% pediatric neurosurgical operative caseload. It is recognized that in an era of increasing neurosurgical subspecialization, children with particular disorders (eg, intracranial aneurysms) may be better served by a specialist experienced with that specific disorder. The pediatric neurosurgeon is usually in the best position to determine the most appropriate balance of care for both the child and condition by virtue of access to other regional pediatric and neurosurgical specialists. With these comments in mind, the following recommendations are suggested for referral of the infant (0–1 year), child (2–12 years), and adolescent (13–18 years) to a pediatric neurosurgical specialist.

- All infants and children requiring neurosurgical operative care should be cared for by a pediatric neurosurgeon if one is within reasonable proximity. However, it is recognized that under some circumstances, the distance to the nearest pediatric neurosurgeon is prohibitive, and it may be necessary for a general neurosurgeon to provide care; the benefits of each option should be considered on an individual basis.
- Infants and children with traumatic head, spine, spinal cord, and peripheral nerve injuries may be stabilized at a local hospital but should then be transferred to a center having both pediatric neurosurgical expertise and a system in place to care for the traumatically injured child. Infants and children with suspected abusive head trauma should also be evaluated by a pediatric neurosurgeon as part of a team of dedicated pediatric child abuse specialists.
- Infants, children, and adolescents with benign and malignant central nervous system tumors (including tumors involving the brain, spinal cord, meninges, spine, pituitary gland, and peripheral nerves) should be referred from the outset to a pediatric neurosurgeon and other dedicated pediatric cancer specialists.
- All infants, children, and adolescents with congenital brain and spinal cord malformations (including spina bifida) should be cared for by a pediatric neurosurgeon as part of a multidisciplinary medical-surgical team (such as a spina bifida clinic).
- All infants, children, and adolescents with disorders of the craniofacial skeleton (eg, craniosynostosis and

craniofacial disorders) should be cared for by a pediatric neurosurgeon as part of a craniofacial team.

- Infants with hydrocephalus, as well as children and adolescents with complex hydrocephalus, are preferably cared for by a pediatric neurosurgeon; those for whom neuroendoscopy is a surgical option should be evaluated by a pediatric neurosurgeon with neuroendoscopy experience.
- Infants, children, and adolescents with intractable epilepsy who are being considered for seizure surgery should be referred to a neurosurgeon having expertise in seizure surgery.
- Infants and children with infections of the central nervous system, including epidural abscess, subdural empyema, or brain abscess, are preferably cared for by a pediatric neurosurgeon in conjunction with specialists in pediatric infectious disease.
- Infants and children with medical conditions that increase operative risk, such as congenital heart disease, who must undergo a neurosurgical procedure should be cared for by a pediatric neurosurgeon with access to other pediatric specialists.

REFERRAL TO A PEDIATRIC OPHTHALMOLOGY SPECIALIST

A pediatric ophthalmologist has completed a residency in ophthalmology, is certified by the American Board of Ophthalmologic Surgery, and has completed additional training of at least 1 year in pediatric ophthalmology. For purposes of developing these recommendations, the following age group definitions are used: infant (0–1 year), child (2–12 years), and adolescent (13–18 years).

Pediatric patients with the following conditions should be referred to a pediatric ophthalmologist:

- children 7 years or younger who are nonverbal or unable to read letters and in whom there is reason to suspect eye disease;
- infants or children with retinoblastoma or other tumors of the eye and orbital area;
- infants or children with known or suspected cataracts, glaucoma, or blindness;
- infants or children with a diagnosis or at risk of retinopathy of prematurity;
- infants or children with congenital or genetic ocular anomalies or infections (eg, aniridia, toxoplasmosis);
- infants or children with systemic syndromes, metabolic disorders, or chromosomal abnormalities with possible ocular involvement (eg, juvenile idiopathic arthritis, galactosemia, diabetes mellitus, Marfan syndrome, Down syndrome); and
- infants or children suspected of being abused and in whom there is a possibility of eye injury.

Pediatric patients with the following conditions are preferably managed by a pediatric ophthalmologist:

- infants with congenital nystagmus and children with early-onset nystagmus;
- children with strabismus or amblyopia (ie, dimness of vision without detectable organic lesion of the eye) or risk factors for strabismus or amblyopia (eg, family history of amblyopia or orbital or eyelid hemangioma);
- children with a family history of congenital or genetic ocular anomalies (eg, aniridia), infections (eg, toxoplasmosis), tumors (eg, retinoblastoma), or a family history of

systemic or metabolic syndromes (eg, juvenile idiopathic arthritis, galactosemia, diabetes mellitus), chromosomal abnormalities (eg, Down syndrome), or other disorders with possible ocular involvement;

- infants or children with exposure during gestation to certain specific drugs or other substances (such as alcohol) that are known to cause anomalies of the eyes;
- infants or children with poor vision or delayed attainment of vision-related developmental milestones and infants and children with severe refractive errors or a strong family history of severe refractive errors; and
- infants or children with ocular or periocular inflammation not responding to initial topical and/or systemic antibiotic therapy or not clearing within 3 weeks of treatment and children with suspected herpes simplex or zoster infections involving the eye or a history of these infections involving the eye.

REFERRAL TO A PEDIATRIC ORTHOPEDIC SURGERY SPECIALIST

A pediatric orthopedic surgeon has completed a residency in orthopedics and completed an additional Accreditation Council for Graduate Medical Education–approved 1-year fellowship in pediatric orthopedics. An orthopedic tumor surgeon has completed a residency in orthopedics, plus additional training in orthopedic oncology, and devotes his or her practice to patients with cancer of the bones and joints. For purposes of developing these recommendations, the following age group definitions are used: infant (0–1 year), child (2–12 years), and adolescent (13–18 years).

The following patients may be best cared for by a pediatric orthopedic surgeon:

- infants with malformations of the limbs (eg, idiopathic clubfoot, congenital limb deficiency);
- children and adolescents with significant limb deformity secondary to metabolic bone disease or other types of growth arrest or with significant limb length discrepancy;
- infants, children, and adolescents with developmental dysplasia of the hip (screening for developmental dysplasia of the hip is performed by the primary care pediatrician);
- infants, children, and adolescents with bone or joint infection (eg, osteomyelitis, septic arthritis), in conjunction with the primary care pediatrician and pediatric infectious disease specialist;
- children with Perthes disease (ie, osteochondritis of the femoral head);
- children and adolescents with slipped capital femoral epiphysis;
- infants, children, and adolescents with significant spinal deformity (scoliosis or kyphosis);
- infants, children, and adolescents with disability, deformity, or gait abnormality secondary to neuromuscular conditions (eg, cerebral palsy, spina bifida, muscular dystrophy, spinal muscular atrophy);
- children and adolescents with sports injuries, such as anterior cruciate ligament tears, meniscal tears, cartilage injuries, ankle instability, or shoulder instability;
- adolescents with deformities or sequelae from childhood musculoskeletal disorders;
- infants, children, and adolescents with multiple skeletal trauma or complex fractures and dislocations; and

- children with musculoskeletal extremity or spine injuries who may be victims of nonaccidental trauma.

Malignant bone tumors should be managed by an orthopedic tumor surgeon, in conjunction with a pediatric medical cancer specialist. Benign bone tumors should be managed by a pediatric orthopedic surgeon or an orthopedic tumor surgeon. Congenital deformities or neuromuscular abnormalities of the upper extremity (including obstetrical brachial plexus injuries) should be managed by a pediatric orthopedic surgeon or a pediatric upper extremity surgeon.

REFERRAL TO A PEDIATRIC OTOLARYNGOLOGY SPECIALIST

A pediatric otolaryngologist has completed a 4- to 5-year residency in otolaryngology/head and neck surgery and is certified by the American Board of Otolaryngologic Surgery. In addition, he or she has completed 1 or 2 years of fellowship training in pediatric otolaryngology. For purposes of developing these recommendations, the following age group definitions are used: infant (0–1 year), child (2–12 years), and adolescent (13–18 years). The following patients should be referred to a pediatric otolaryngologist, although a pediatric plastic surgeon, pediatric surgeon, pediatric dentist, or pediatric oromaxillofacial surgeon with appropriate education, training, and experience would also be appropriate in some cases:

- infants, children, and adolescents with congenital malformations of head and neck structures, including the ear, nasal passages, oral cavity, and laryngotracheal airway;
- infants and children with sensory impairments, including conductive or sensorineural hearing loss, vestibular disorders, unilateral and bilateral true vocal fold paralysis,

facial nerve paralysis, and oromotor dysfunction as evidenced by speech, swallowing, or drooling problems;

- infants and children with acquired otolaryngologic disorders involving the ear (eg, cholesteatoma), the pharynx, the laryngotracheal airway (eg, postintubation laryngotracheal stenosis), the aerodigestive tract (eg, foreign body aspirations), and the facial skeleton (eg, maxillofacial trauma);
- infants, children, and adolescents with neoplasms or vascular malformations of the head and neck structures, including the laryngotracheal airway;
- infants and children with medical conditions that increase operative risk (eg, congenital heart disease) who must undergo a common otolaryngologic procedure (eg, adenotonsillectomy); and
- infants and children requiring operative airway endoscopy for the evaluation of stridor.

The following patients are preferably managed by a pediatric otolaryngologist:

- infants and children with complicated infections that may require surgery involving the ear (eg, otitis media with effusion and hearing change), the nose and paranasal sinuses (eg, chronic rhinosinusitis), the pharynx (eg, recurrent adenotonsillitis), the airway (eg, epiglottitis), and the neck (eg, retropharyngeal abscess).

REFERRAL TO A PEDIATRIC PLASTIC SURGERY SPECIALIST

A pediatric plastic surgeon is certified by the American Board of Plastic Surgery. He or she has completed the requirements of residency training for board certification in plastic surgery (usually a total of 6 or more years of

surgical and surgical specialty training) plus an additional year training in pediatric plastic surgery and/or pediatric craniofacial surgery, although it is recognized that some general plastic surgeons and occasionally pediatric surgical specialists have the requisite education, training, and experience to deal with some of these problems. For purposes of developing these recommendations, the following age group definitions are used: infant (0–1 year), child (2–12 years), and adolescent (13–18 years). Infants, children, and adolescents with congenital malformations of head and neck structures, including the skull (ie, deformational plagiocephaly or craniosynostosis, among others), eyes (ie, micropthalmia, eyelid ptosis), ears (ie, prominent ear deformity, microtia), nose (ie, dermoid lesions, arhinia), mouth (ie, clefts of the lip and palate), and jaws (ie, malocclusion, hemifacial microsomia), should be referred to a pediatric plastic surgeon.

- Infants and children with congenital malformations of the limbs (eg, syndactyly, polydactyly) should be referred to a pediatric plastic surgeon.
- Infants, children, and adolescents with major or significant burns or injuries should be stabilized at a local hospital and then transferred to a pediatric burn/trauma center with a pediatric plastic surgeon as part of the treatment team.
- Infants, children, and adolescents with trauma to the hand, specifically including bone, tendon, and skin injuries, should be referred to a pediatric plastic surgeon.
- Infants, children, and adolescents with large cutaneous pigmented or vascular lesions (eg, nevi, port wine stains, arteriovenous malformations) should be referred to

a pediatric plastic surgeon or other pediatric surgical specialist with the appropriate education, training, and experience.

- Infants, children, and adolescents with large bone or soft tissue tumors that, when excised, leave defects requiring tissue transfer or reconstruction are preferably cared for by a pediatric plastic surgeon.

The pediatric plastic surgeon is optimally part of a multispecialty team (with pediatricians and other pediatric surgical specialists) in management of conditions such as myelomeningocele or complex problems requiring tissue expansion or microsurgical procedures.

REFERRAL TO A PEDIATRIC SURGEON

A pediatric surgeon has completed a 5-year residency training in general surgery, plus a 2-year fellowship in pediatric surgery. He or she is certified by the American Board of Surgery and has further specialized in the surgical treatment of children. The American Board of Surgery now offers a subspecialty certificate in pediatric surgery that can be earned by those Diplomates of the American Board of Surgery who have specialized in pediatric surgery. For purposes of developing these recommendations, the following age group definitions are used: infant (0–1 year), child (2–12 years), and adolescent (13–18 years).

- Patients 5 years or younger who may need surgical care should be cared for by a pediatric surgeon.
- Seriously injured infants and children may be stabilized at a local hospital and then should be transferred to a pediatric trauma center.
- Infants, children, and adolescents with solid malignancies should be

cared for from the outset by a pediatric surgeon or pediatric surgical specialist and a pediatric medical cancer specialist.

- Minimally invasive procedures (eg, laparoscopy, thoracoscopy) in infants and children should be performed by a pediatric surgeon trained in these techniques.
- Infants and children with medical conditions that increase operative risk (eg, congenital heart disease, preterm birth) who must undergo a common surgical procedure (eg, hernia repair) should be cared for by a pediatric surgeon.

In the interest of good patient care, it is suggested that a general surgeon who cares for pediatric surgical problems not listed in the above categories should have had a minimum 6-month rotation as a junior or senior resident during his or her general surgical residency on a pediatric surgical service run by a pediatric surgeon. Emphasis in the training rotation should be on surgery in children older than 5 years.

A general surgeon performing surgery in children not listed in the above categories should care for a sufficient number of children annually to maintain a high level of competence and should annually attend pediatric surgery postgraduate courses and meetings.

REFERRAL TO A PEDIATRIC UROLOGIST

A pediatric urologist has completed training in urology, is certified by the American Board of Urology, and has completed a 2-year pediatric urology fellowship. The American Board of Urology now offers a subspecialty certificate in pediatric urology that can be earned by those Diplomates of the American Board of Urology who have specialized in pediatric urology. This

certificate recognizes training and experience in the care of individuals with pediatric urologic conditions of all ages. The development of formal training programs and the availability of subspecialty boards in pediatric urology are relatively recent. Some urologists may have gained a lifetime of pediatric experience, but started practice before such fellowships were available. For purposes of developing these recommendations, the following group definitions are used: infant (0–1 year), child (2–12 years), and adolescent (13–18 years).

- Undescended testicles and elective congenital hydrocele/hernia are optimally corrected in infancy or early childhood; the operation should be performed by a pediatric urologist or surgical specialist.
- Hypospadias is usually repaired in infancy or early childhood; the operation should be performed by a pediatric urologist.
- Complex congenital urologic problems (eg, duplex systems, ureterocele, bladder or cloacal exstrophy, moderate or severe vesicoureteral reflux, posterior urethral valves, or other structural abnormalities of genitourinary development, such as persistent genitourinary sinus or cloacal abnormalities) should preferably be managed by a pediatric urologist.
- Solid malignancies of the kidney, bladder, and testicle should be treated from the outset by a pediatric urologist or surgical specialist in conjunction with a pediatric medical cancer specialist.
- Disorders of sex development should be comanaged from the outset by a pediatric urologist or surgical specialist in conjunction with a management team, which should include a pediatric endocrinologist and a psychologist,

in consultation with the primary care pediatrician.

- Cystoscopic procedures in infants and children preferably should be performed by a pediatric urologist.
- A pediatric urology consultation should be considered when a child has prolonged, severe daytime voiding difficulty.
- A pediatric urologist should be involved in the care of children with spinal cord disorders (eg, myelomeningocele, spinal cord injuries).
- Infants or children with major urologic injuries should be stabilized at the nearest medical center and then transported to a pediatric trauma center.
- Infants or children with testicular torsion should be evaluated at the nearest medical center and undergo surgery promptly.
- When a urinary tract abnormality has been identified prenatally, a pediatric urologist or surgeon should be consulted as a member of the fetal treatment team, preferably prenatally or as early postnatally as is feasible.

REFERRAL FOR ENDOSCOPY

Specialists in several pediatric surgical and pediatric medical fields are

trained to perform endoscopic procedures in infants and children. For purposes of developing these recommendations, the following age group definitions are used: infant (0–1 year) and child (2–12 years).

- Endoscopy of the airways (eg, bronchoscopy, laryngoscopy) in infants and children should be performed by a pediatric surgeon or a pediatric otolaryngologist or an appropriately trained pediatric medical specialist, which may include a pediatric pulmonologist or a pediatric intensivist.
- Esophagoscopy in infants and children should be performed by a pediatric surgeon, a pediatric otolaryngologist, or a pediatric gastroenterologist.
- Endoscopy of the gastrointestinal tract distal to the esophagus (eg, esophagogastroduodenoscopy, colonoscopy) in infants and children should be performed by a pediatric surgeon or a pediatric gastroenterologist.

Because the care of infants, children, and adolescents changes and advances rapidly, these recommendations should be updated at regular intervals.
